NAVY DEPARTMENT CONTRACT NXs860008

BUREAU OF SHIPS
APPROVED DEC. 10, 1945

B 38387

NAVY DEPARTMENT

BUREAU OF SHIPS WASHINGTON 25, D. C.

12 December, 1945

SECURITY NOTICE

"NAVSHIPS 900,841" is a restricted non-registered publication and shall be handled, transported, and safeguarded in accordance with U. S. Navy Regulations. When superseded by a later edition, this publication shall be destroyed.

Any person known to be in the service of the United States and persons of undoubted loyalty and discretion who are cooperating in Government work shall have access to this publication. However, information contained herein shall not be communicated to the public or to the press.

This document contains information affecting the National defense of the United States within the meaning of the Espionage Act, 50 U. S. C., 31 and 32, as amended. Its transmission or the revelation of its contents in any manner to an unauthorized person is prohibited by law. (ART, 76, U. S. N. REGS.—1920)

Extracts from this publication may be made to facilitate the preparation of other Navy instruction books and handbooks.

Copies of this publication should be obtained from the nearest Electronics Officer.

E. L. COCHRANE Chief of Bureau

NOTICE

This equipment has neither crystals nor crystal ovens included in this shipment. These items are required for the operation of this set and are government furnished items.

Requisition the crystal ovens from:

Supply Officer (Electronics)
Naval Supply Depot
Mechanicsburg, Pennsylvania

2 Crystal Ovens Navy type CFT 40148

The crystals for this unit may be taken from the companion Model MAR Equipment Spares.

CONTRACTUAL GUARANTEE

The Contractor guarantees that at the time of delivery thereof the articles provided for under this contract will be free from any defects in material or workmanship and will conform to the requirements of this contract. Except as to vacuum tubes, batteries, rubber and material normally consumed in operation, the equipment, including all spare parts, is guaranteed for a period of one (1) year from the date of its delivery to and acceptance by the Government, with the understanding that all items found to be defective as to material, workmanship or manufacture will be repaired or replaced f.o.b. any point within the continental limits of the United States designated by the Government, without delay and at no expense to the Government; provided, that such guarantee shall not obligate the Contractor to repair or replace any such defective items unless the defect appears within the aforementioned period and the Contractor is notified thereof in writing within a reasonable time and unless the defect is not the result of normal expected shelf life deterioration. This guarantee shall then continue as to corrected or replacing articles or, if only parts of such articles are corrected or replaced, to such corrected or replacing parts, until one year after the date of redelivery.

To the extent the equipment, including all parts and spare parts, as defined above, is of the Contractor's design or is of a design selected by the Contractor, it is also guaranteed, subject to the foregoing conditions, against defects in design, with the understanding that if ten per cent (10%) or more of the total quantity comprising such item furnished under the contract (but not less than two thereof) is found to be defective as to design, the entire item will be conclusively presumed to be of defective design and shall be subject to one hundred percent (100%) correction or replacement by a suitably redesigned item.

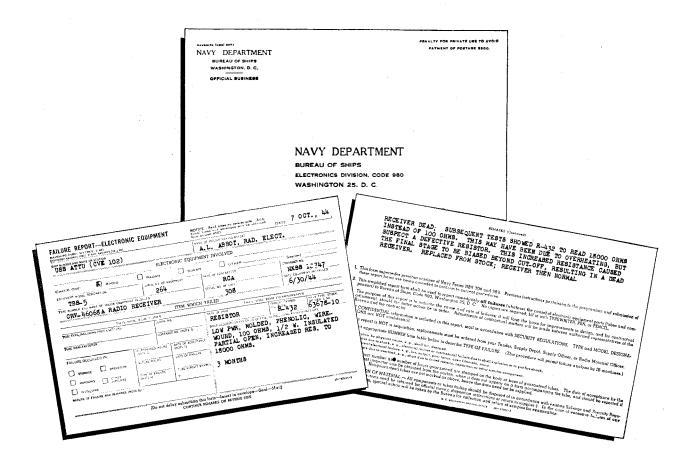

All defective items will be subject to ultimate return to the Contractor except that the exigencies of the naval service may necessitate expeditious repair of certain items in order to prevent extended interruption of communications and in such cases the return of the defective items for examination by the Contractor prior to repair or replacement shall not be mandatory. The report of a responsible authority, including details of the conditions surrounding the failure, will be acceptable as a basis for effecting expeditious adjustment under the provisions of this contractual guarantee.

INSTALLATION RECORDS

Contract No. NXsr-60008	Dated 4 May, 1944
Serial Number of equipment	
Date of acceptance by the Navy	
Date of delivery to contract destination	······································
Date of completion of installation	
Date placed in service	

Blank spaces in this book shall be filled in at the time of installation. Operating personnel shall also mark the "date placed in service" on the date plate located below the model nameplate on the equipment, using suitable methods and care to avoid damaging the equipment.

FAILURE REPORTS

A FAILURE REPORT must be filled out for the failure of any part of the equipment (except tubes) whether caused by defective or worn parts, improper operation, or external influences. It should be made on Failure Report, form NBS-383 (Rev. 3-45), which has been designed to simplify this requirement. The card must be filled out and forwarded to BUSHIPS in the franked envelope which is provided. Full instructions are to be found on each card.

Use great care in filling the card out to make certain it carries adequate information. For example, under "Circuit Symbol" use the proper circuit identification taken from the schematic drawings, such as T-803, in the case of a transformer, or R-207, for a resistor. Do not substitute brevity for clarity. Use the back of the card to completely describe the cause of the failure and attach an extra piece of paper if necessary.

The purpose of this report is to inform BUSHIPS of the cause and rate of failures. The information is used by the Bureau in the design of future equipment and in the maintenance of adequate supplies to keep the present equipment going. The cards you send in, together with those from hundreds of other ships, furnish a store of information permitting the Bureau to keep in touch with the performance of the equipment of your ship and all other ships of the Navy.

This report is not a requisition. You must request the replacement of parts through your Officer-in-Charge in the usual manner.

Make certain you have a supply of Failure Report cards and envelopes on board. They may be obtained from any RMO.

ORDERING PARTS

All requests or requisitions for replacement material should include the following data:

- 1. Navy stock number or, when ordering from an Army supply depot, the Army stock number.
- 2. Name of part.

If the Navy stock number has not been assigned, the requisitions should specify the following:

- 1. Equipment model designation.
- 2. Name of part and complete description.
- 3. Manufacturer's designation.
- 4. Contractor's drawing and part number.
- 5. AWS, JAN, or Navy type designation.

SAFETY NOTICE

WARNING

This equipment employs voltages which are dangerous if contacted by operating personnel. Extreme caution should be exercised when working with the equipment.

change tubes or make adjustments inside the equipment with high voltage supply on. Do not depend upon switches for protection but always shut off power supply. Dangerous potentials may exist in the circuits with power controls in the off position. To avoid casualties always remove power, discharge and ground circuits prior to touching them.

DONT service or adjust alone. Under no circumstances should the equipment be serviced without the immediate presence of another person capable of rendering aid. In testing circuits, check for continuity and resistance in preference to checking voltages.

ATTENTION

Officers and operating personnel are directed to Chapter 67 of Bureau of Ships or superseding instructions on the subject of "Radio Precautions to be Observed."

NOTICE

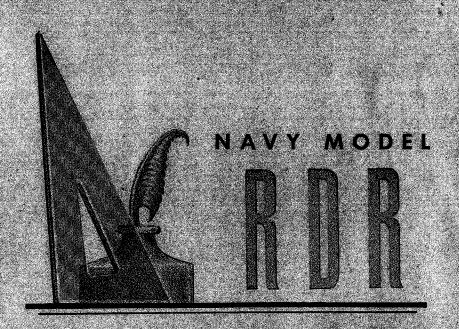

An approved poster illustrating the rules for resuscitation by the prone pressure method shall be prominently displayed in each radio, radar or sonar enclosure. Posters may be obtained upon request to the Bureau of

ORIGINAL RESTRICTED 1-1

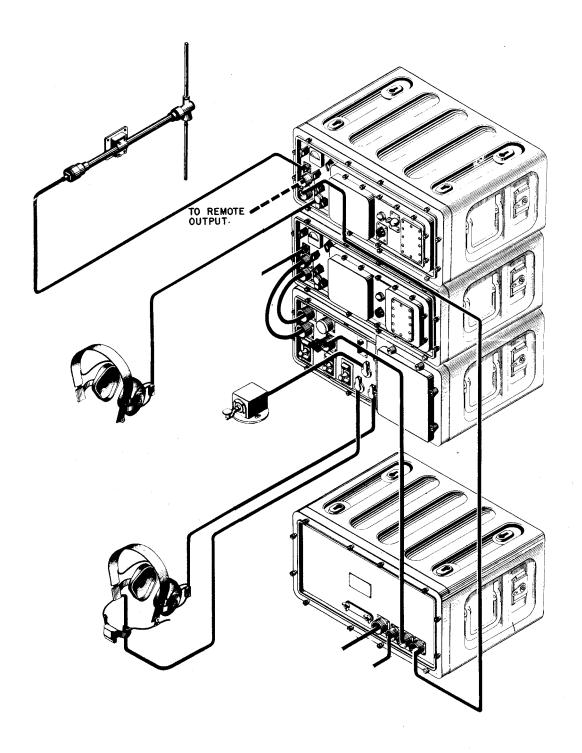

The RDR radio receiver was developed as a companion receiver for the MAR radio equipment. It is identical in appearance with the exception of an additional switch on the panel for switching the receiver off when not required.

The case of the RDR is the same corrugated metal enclosure as used with MAR, fitted with handles on the ends and keyhole slots on top and bottom of the case. Thus, the RDR may be mounted on a shockmount and combined with MAR equipment, in shipboard applications.

The case is fitted with a watertight cover held in place with heavy thumbnuts, a screwdriver and Allen wrench being clipped to the ends of the case, to be used for loosening or tightening the lid clamping screws.

The characteristics of the RDR are identical to those of the receiving section of the MAR, employing a similar circuit with its choice of ten crystal-controlled pre-set frequencies, any of which are available by simply rotating the selector switch to the frequency channel desired. The frequencies covered range from 225 to 390 megacycles. The motor-driven tuning mechanism control circuits are arranged to permit the connection of a remote selector switch so selection of channel frequency is possible from remote points.

RDR SHIPBOARD APPLICATION

When used in conjunction with the MAR installations on shipboard, the RDR is powered from an outlet, provided for the purpose, on the panel of the Universal Power Supply unit. The unit then furnishes the 13 volt filament current required for the receiver and high voltage direct current for plate circuits of the tubes and selector motor operation.

The receiver may be powered direct from a 13 volt, direct current source. To obtain plate and selector motor voltages under this condition, use is made of the dynamotor in the receiver chassis. The power switch on the receiver starts the dynamotor when moved to the proper position in switching on the equipment.

The RDR receiver, when used on shipboard, is mounted on the framework supporting the MAR equipment by means of a shockmount not shown in the illustration opposite. The equipment components and operating accessories furnished are listed in the table below.

As will be seen, a cable is furnished to connect the RDR to the outlet on the universal power unit. This is the usual form of installation but where operation from 13 volt direct current is necessary, a second short cable is supplied to adapt a two wire battery cable to the 9 point input jack on the receiver.

The adaptor cable takes care of conditions when the receiver may be used in conjunction with field installations, where a gas engine generator is employed as the power source of the equipment.

The antenna accessories include a 10 foot coaxial transmission line, fitted with plugs and ready to install between antenna and receiver. For installations requiring longer transmission lines, a similar coaxial cable 50 feet long fitted with plugs is provided with the equipment accessories.

The two lengths of transmission line cable may be connected together by a connector, also furnished, to form a single transmission line.

TECHNICAL SUMMARY

RDR RECEIVER—NAVY TYPE CRV-46283

Frequency Range	225-390 Megacycles
Frequency Stability	$\pm0.007\%$
Tuning Bands	1
Pre-set Frequencies	. 10
Type of Circuit	Superheterodyne
Crystals	10, oven mounted
Sensitivity	10 microvolts
Selectivity	250 kc bandwidth at 6 db
Silencer Circuit	Operates on 6 db change
Input Voltage	13 V d-c or 13 V a-c and 375 V d-c
A-F Impedance	600 ohm output
A-F Output Frequencies	300-3000 cycles
Output Power	l watt

DETAILS OF RECEIVER ASSEMBLY

The receiver is completely sealed by the watertight cover that must be removed while the equipment is in operation. Tools are clipped to the ends of the cases, to loosen the thumbscrews holding the cover in place.

1 SECTION

Removal of the cover exposes the controls of the receiver, grouped at the left of the panel. The panel mounts the Output control, Silencer level control and switch, Antenna compensator and the meter and its associated switch. Receptacles for connecting antenna, power and output cables, and a jack for the headset are mounted on the panel.

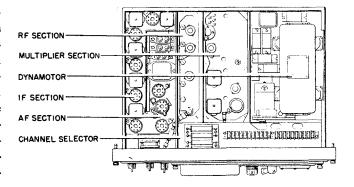

At the right of the receiver panel is another remov-

able cover which remains in place for normal operation. This cover protects the crystal oven and automatic tuning selectors and mounts the panel light and knobs for the channel selector switch and power switch.

With the cover in place over the selector mechanism the equipment is splash proof and can be operated under any condition of the weather. Silica gel dryer units absorb any moisture that might seep into the receiver case.

THE CHASSIS

To facilitate repairs and replacement of the functional units that make up the receiver, the chassis is arranged with partitions that serve well as shielding between the various circuits. As will be seen in the illustration of the top of the chassis, the circuit elements are grouped in sections that form, in several cases, units that may be removed as a whole from the chassis for repairs, adjustment or replacement. The dynamotor for generating the plate current is mounted at the right, in the position occupied by the transmitter elements in the MAR assembly of receiver and transmitter.

1-8

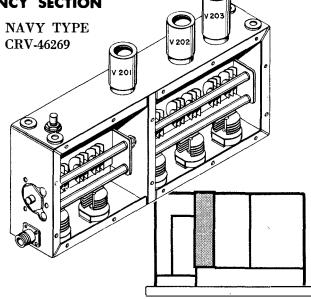

RADIO FREQUENCY SECTION

The radio frequency section of the receiver shown on this page consists of one radio frequency stage tuned to signal frequency, V201, the third tripler for the heterodyning frequency, V203, and the 1st detector or mixing tube, V202.

The above tubes are mounted on the top of the metal case that carries in its interior a gang of ten variable capacitors and associated tuning inductances. The capacitors are grouped in 5 pairs, each pair, with its associated inductance, forming the tuning element of one of the five resonant circuits involved.

The tuned antenna circuit is inductively coupled to the tuned input circuit of the radio frequency amplifier tube V201. The coupling is such as to provide maximum signal gain consistent with good selectivity. The output circuit of the RF amplifier stage is tuned and coupled inductively to the tuned input circuit of the first detector. This second tuned coupling arrangement acts to improve the signal to noise ratio and maintain selectivity against image and other spurious responses.

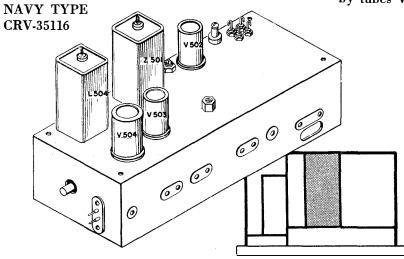

Another pair of variable capacitors is used to tune the plate circuit of the heterodyning frequency tripler, V203, the output of which is inductively coupled into the 1st detector, V202, to obtain the heterodyning action in the latter tube.

The ganged capacitors in the unit are driven through a shaft that extends from the end of the assembly and couples to the selector marked RF. on the tuning panel. Proper alignment of the circuits is accomplished by means of trimming and padding capacitors adjustable from the top and bottom of the unit. A small antenna trimmer capacitor is also mounted in this unit and coupled to the knob on the control panel by means of a geared shaft assembly, as seen in the top view of the chassis.

FREQUENCY MULTIPLIER SECTION

The purpose of this section is to provide the proper heterodyning frequency for the receiver. A crystal in the crystal oven on the panel, selected by the selector switch in conjunction with the automatic

tuning mechanism, is the control for the fundamental frequency of the oscillating circuit formed by a pair of grids of the tube V504. This frequency is doubled in the plate circuit V504 and tripled twice by tubes V503 and V502. The output current of

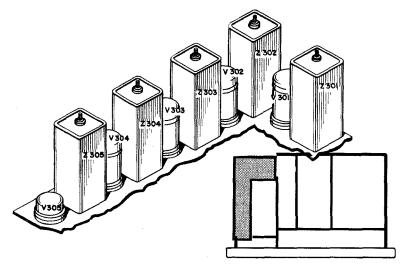

> V502 is fed into a third tripler located in the radio frequency section, thus providing the heterodyning frequency for the receiver.

The two coupling transformers for the multiplying stages are shown on top of the chassis, adjustable cores being used in these units. The variable capacitors for tuning the frequency multiplying circuits are ganged and mounted inside the case of the unit. The capacitors are coupled to the multiplier selector on the panel by means of a shaft extending from the end of the casing.

INTERMEDIATE FREQUENCY AMPLIFIER SECTION

The inverted L section at the left of the chassis contains the transformers and tubes of the intermediate frequency amplifier and the second detector. Five fixed-tuned transformers, fitted with adjustable cores and fixed capacitors serve to couple the four stages of amplification and diode detector, V305.

From the output of the 1st detector in the RF section, the transformer T301 selects the 30.2 megacycle difference frequency for amplification. Four tubes, V301, V302, V303 and V304, coupled by the associated transformers, provide high amplification to feed the 2nd detector, V305. This latter tube is a double diode and provides AVC control as well as functioning as detector.

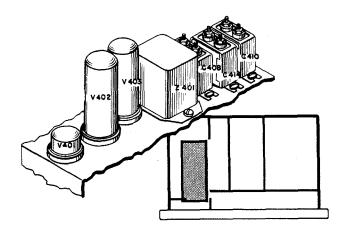

Necessary by-pass capacitors, biasing and filter resistors for the amplifier are mounted beneath the chassis, readily accessible from the bottom.

AUDIO FREQUENCY AMPLIFIER SECTION

The three tubes in the audio frequency section of the receiver function as noise peak eliminator, meter rectifier and silencer in addition to providing two stages of audio frequency amplification. The equipment is designed for headset reception so the audio gain need not be great or the output high. but 1 watt output is available for loudspeaker operation if desired. Filtering networks are included to cut off the higher audio frequencies to reduce hiss, while an output band pass filter holds the audio frequencies within the 300 to 3000 cycle frequency range.

The first tube in this section, V401, is a double diode, one section being connected to act as a rectifier in conjunction with the panel meter circuit when readings are taken with a-c supply. The second section of the tube acts as a noise peak eliminator, cutting off signals during noise peaks.

The second tube, V402, is a double triode, one section acting as the "silencer" amplifier, the other as the first stage of audio amplification. The silencer section of the tube functions to control the bias on the grid of the amplifying section of the tube to

render it inoperative and the receiver silent during no signal periods.

The final stage of audio amplification is obtained in tube V403, its output being coupled through the filtering network to the output circuit of the equipment. The output of the receiver is fed to the output receptacle on the panel and also connected to a phone jack located on the panel of the equipment.

AUTOMATIC CHANNEL SELECTOR

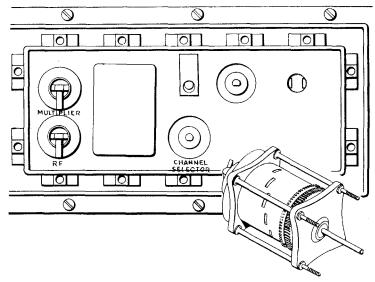

The automatic tuning or channel selector mechanism is a compact motor driven device occupying the space behind the panel at the right of the chassis. The illustration shows the appearance of the unit with front panel removed. An additional view is given of a selector unit, which shows the shaft extending at the rear for coupling to the driven tuning components of the receiver circuits.

The selectors can be set to a series of ten frequencies, as determined by the crystals provided, by a sequence of adjustments. This involves the setting of the channel se-

lector switch on the first point, the tuning mechanism driving switches that connect a crystal from the bank of ten in the crystal oven into the oscillator circuit and positions the selectors for the first tuning sequence. The selector dials are then unlocked by raising the lever on the dials and the equipment tuned to the frequency selected, using the panel meter to determine resonance points. The dials are relocked by depressing the levers. A setting of the channel selector switch is made for another frequency and the process of unlocking, tuning and locking the dials repeated. In this manner it is possible to pre-tune the equipment for the ten frequencies within the 225 to 390 megacycle band, any of which being available for use by simply rotating the selector switch to the frequency desired.

The mechanism is driven by a small motor in the rear, visible in the top view of the chassis. The sequence of operation is as follows. When the Channel Selector switch is moved to change the frequency, a section of the switch operates a relay to close the motor circuit. The motor turns the selector drums and the crystal selecting switch to a new position by means of worm and spur gears.

The rotating mechanism also drives a homing switch which acts to open the relay circuit when it reaches a point corresponding to the position of the selector switch. The opening of the relay circuit causes the relay armature to drop back and another set of contacts is closed that reverses the

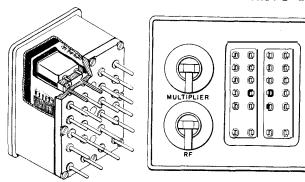

motor. The motor continues running in the reverse direction. When it has returned to its original position the limit switch, shown in the illustration, is actuated by the arm, opening the motor circuit and stopping the motor in position for another tuning excursion.

Terminals are provided on the bottom of the unit so an external selector switch may be connected to the equipment for remote selection of channel frequency.

The selectors operate as follows. In the forward direction the motor drives an outer drum, on each selector, that has ten slots. Each slot corresponds to one of the positions of the selector switch. Thus, the slot corresponding to the position selected will stop in the proper location. A pawl for the position selected will be cocked and when the motor reverses, the shaft to the tuned element carrying a bank of notched discs will also rotate, the drum remaining positioned, until the notch in the disc associated with the cocked pawl lines up with it. Then the pawl will drop into the notch and hold the shaft of the capacitor or other driven device at the desired position. As the motor drive continues in the reverse direction, a slipping clutch permits the selector disc and shaft to the tuned element to remain correctly positioned with the pawl latched into the proper disc. The motor operates until the mechanism strikes a limit switch and the motor stops. In this position the pawls will be locked in and the equipment tuned to the new frequency.

THE CRYSTAL OVEN

NAVY TYPE CFT-40148

The ten crystals controlling the basic frequency generated in the oscillator section of V504 are grouped and mounted in the compact unit shown in the illustration. The crystals are of the hermetically sealed miniature type CR-7E/U and the terminal pins of the individual crystal holders fit into jacks inside the unit that connect to pins on the rear of the unit. The cover may be removed from the unit for the replacement or installation of individual crystal holders.

The crystal oven has two built-in thermostaticallycontrolled heating units to maintain the crystals at a practically fixed temperature which prevents any shift in frequency that might occur with a change in crystal temperature.

Of the two heating units provided, one is a booster unit intended to bring the temperature of the oven to operating temperatures as rapidly as possible when the equipment is first switched on. When the proper temperature has been reached the booster heater cuts off and the second heating unit functions to take care of any further fluctuations of temperature.

The crystal oven is fitted with twenty-four pins at the rear, twenty of the pins connecting to the ten pairs of crystal terminals while the other four pins are the heating unit terminals. The crystal oven plugs into a jack panel in the receiver selector unit, as shown in the illustration, to make the necessary connections to the switching mechanism behind the jack panel. The crystal switching mechanism is coupled to the tuning-motor gear-train and functions to connect the proper crystal into the circuit for any setting of the selector dials.

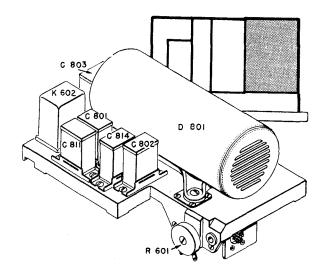

THE DYNAMOTOR

NAVY TYPE CAY-211483

The remaining section of the receiver chassis mounts the dynamotor, a device to provide the high voltage direct current for the tube plates and selector motor operation. This unit is essentially a motor-generator, in that it consists of a 13 volt, series wound motor at the input end that operates from the 13V, direct current power source. The output side is a 385 volt, direct current generator with a full load rating of 500 milliamperes.

Filter components, consisting of choke coils and capacitors, are provided to remove all commutator ripple from the generator end of the machine and suppress any brush noise generated in the motor that would cause interference in the receiver circuits.

The dynamotor is used only with a 13V, direct current power supply. The power switch on the panel of the receiver is arranged to switch the

dynamotor on when moved to the Dyn. position and close the high voltage output circuit of the ma-

chine. When the RDR receiver is used with the MAR equipment and is operated from the universal power unit, the dynamotor is not required. The power switch is then placed on the PU position, when the receiver is placed in operation, and all power for operation is obtained from the power supply unit, both 13V a-c for the heater circuit and 375V d-c for tube plates.

The dynamotor is housed in a crackle finished black case with ventilating louvers in the ends. The frame supporting the dynamotor is carried by four rubber shockmounts that absorb any vibration that may develop in the machine and affect the operation or life of the receiver parts or tubes.

Leads from the dynamotor are connected to a terminal block under the chassis, where connections are made to the filter capacitors which are visible on top of the chassis, grouped around the dynamotor.

The unit is cooled by an inbuilt fan that circulates air through the housing and in so doing puts all the air inside the airtight receiver case into motion. This results in a general overall cooling effect in that maximum radiation is obtained from the metal enclosure of the receiver.

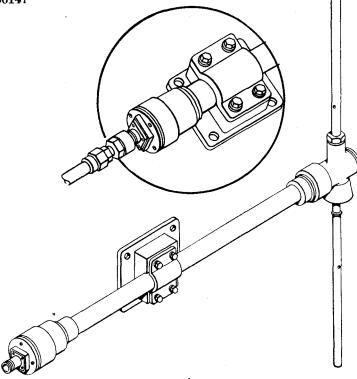

The motor end of the dynamotor is protected by a 30A cartridge fuse; the generator is protected from overload due to short circuits by a 1A cartridge fuse. The latter fuse remains in the circuit when operating from the power unit.

ANTENNA

NAVY TYPE CRV-66147

The antenna is of the halfwave, center-fed dipole type and is furnished disassembled in a carrying case with necessary brackets, accessories and wrench for assembly and installation. The two radiating rods extend at right angles from the end of the tubular mounting member and are screwed into threaded studs for assembly. One rod is grounded to the supporting tube and outer conductor of the coaxial transmission line. The "live" rod is supported by an insulated stud connected to the center lead of the antenna.

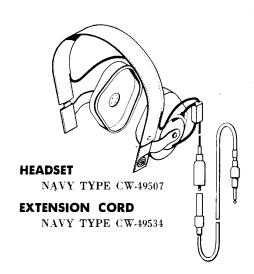

The antenna is designed to have an impedance of approximately 50 ohms with characteristics that result in good matching with the transmission line over the full frequency range of 225 to 390 megacycles used in the equipment. No alterations or adjustments of the antenna are necessary when frequency changes are made.

HEADSET AND EXTENSION CORD

The only operating accessory required with the receiver is the headset, which, due to its short connection cord, requires an extension cord to give freedom to the operator.

The headset hand is leather covered, adjustable as to length over the head, with the earpieces offset from the headband itself. The unit is splashproof and is fitted with snap fasteners so a lip microphone may be clipped into place should it be required.

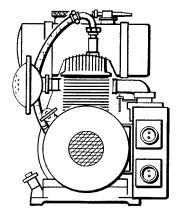

REMOTE OUTPUT

A receptacle is provided on the panel at the lower left to permit connecting the output of the receiver to some remote point and provide remote control of the silencer circuit. This connection requires a three conductor cable, which is not furnished with the equipment. A plug is furnished as an accessory to be attached to the cable and plugged into the receptacle marked REM on the panel.

GAS ENGINE DRIVEN GENERATOR

NAVY TYPE

A self contained generating unit consisting of a four cycle gas engine directly connected to a direct current generator is used as a source of power when the RDR equipment is used in the field or other isolated position where other sources of power are not available.

The power unit fits into a light weight metal carrying case having corrugated sides and a gasketed end cover held in place by eight thumbscrews. The

entire assembly forms a lightweight, portable power plant, rugged enough to stand the hard usage given portable equipment in the field or in Naval service. The unit in its case is completely waterproof and buoyant in fresh water. With the unit removed from its case for operation it is completely splashproof and capable of operation out of doors in any kind of weather for extended periods of time.

As shown in the illustration, the engine is a single cylinder, 4 cycle, air cooled unit, capable of delivering 0.9 HP under continuous duty. It is complete with fuel tank of sufficient capacity to operate the engine for two hours and employs high tension magneto ignition. A switch for cutting off the ignition is mounted on the flywheel housing.

Intended for operation under all conditions of dust, dirt, shock, humidity and extremes of temperature, it is fitted with a readily serviced air intake filter of the dry type and shielded ignition leads and plug. Provisions are also made to allow the unit to be transported in a tilted or inverted position without danger of the fuel or oil leaking or spilling.

The generator with a nominal rating of 30 amperes at 13.7 volts has an output of 13.3 volts direct current under a continuous load of 300 watts with sufficient overload capacity to carry a maximum load of 400 watts for several hours, in case of emergency, without damage.

Both mechanical and electrical regulators are provided to control the output of the unit. The gas engine is fitted with a mechanical governor to maintain a constant engine speed of 4200 R. P. M. Since the unit may be used not only as a source of current for the operation of portable radio equipment but for battery charging as well, two types of regulation on the output of the generator are provided.

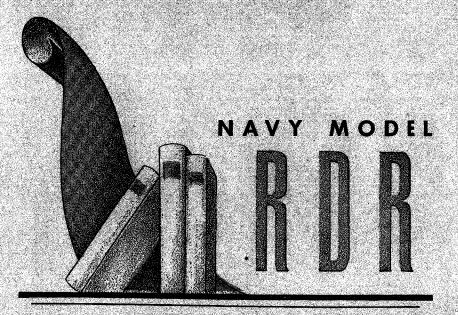

A control box alongside the generator contains the reverse current relay, filter elements and regulator

elements. A toggle switch on the box is arranged to select the type of regulation desired and its two positions are marked "Radio" and "Battery Charge Only." The control box likewise mounts the two output connectors for the connection of cables to the radio equipment and to storage batteries, if the latter are employed with the engine driven unit.

The filter elements and shielding of the ignition prevent commutator ripple and radio frequency interference with the radio equipment. The storage batteries, when available, aid the filtering action by floating on the line and act as stand-by for short operating periods.

The power unit is packed in a heavy luggage type carrying case which contains all accessories, operating spares and servicing tools.

ORIGINAL RESTRICTED 2-1

ANALYSIS OF RECEIVER CIRCUITS

The RDR receiver is of the superheterodyne type as employed in the MAR equipment and in general follows the arrangement of components usually employed in circuits of this type. Certain modifications have been made to assure stable operation under extremes of operating conditions, and at the high frequencies involved in the radio-frequency sections of the equipment. This applies equally to the channel frequency input, the heterodyning frequency generation, and to the intermediate-frequency amplifiers.

To reduce heterodyning frequency drift to a minimum, a crystal-controlled, frequency multiplier is utilized. The crystal controlling the first oscillator frequency is further maintained at a practically-constant temperature by a crystal oven to assure frequency stability under all conditions of operation. This precaution is necessary because the fundamental crystal frequency must be doubled once and tripled three times to derive the heterodyning frequency required by the receiver, which operates on a 30.2 megacycle intermediate frequency.

The receiver circuits include, in addition to automatic volume control, a noise-peak limiter for blocking high-intensity periodical interference often encountered. A silencer circuit is also provided to render the receiver silent during no-signal periods, a desirable feature for headset reception in the high-frequency bands.

Tuning of the receiver is accomplished by means of a motor-driven mechanism that allows of rapid choice of any one of the ten channel frequencies to which the equipment can be set. This arrangement, in connection with the other features of AVC, noise peak suppression, and silencer circuit, results in a receiver particularly suited to remote operation and to a wide range of operating conditions.

On the opposite page is given a block diagram of the receiver circuit in conjunction with a view of the chassis that illustrates the relationship of the circuits involved as well as the location of the sections in the chassis. The circuits have been grouped into functional units for ease of alignment and repair. The entire circuit breaks down into four definite sections that will be discussed in detail.

As will be seen in the block diagram, there is one stage of channel frequency amplification before the first detector tube in the radio-frequency section of the receiver.

The heterodyning frequency for mixing in the detector tube originates in the frequency-multiplier section and involves a crystal-controlled oscillator stage, a doubler, and two tripler stages in this section. This frequency must be tripled again in the R-F section before it is fed to the first detector.

The output of the first detector then passes to the intermediate-frequency amplifier section which consists of four stages of amplification and a diode second detector. This detector tube is of the double-diode type and one section provides the AVC for maintaining a flat-gain characteristic in the amplifier.

The audio-frequency amplifier section contains three tubes that perform five functions as indicated. Here are located the noise suppressor and silencer circuits in addition to the two stages of audio amplification. A section of one of the tubes is utilized as a rectifier for the panel meter to permit readings to be taken on AC supply voltages.

The dynamotor section of the chassis contains the source of high-voltage direct current for the operation of the equipment when operating on a 13 volt, direct-current source. The dynamotor generates the 375V direct current for the tube plate circuits and the selector motor. Filter circuits and control relays are also located in this section.

The channel-selecting mechanism occupies the front section of the chassis and includes the crystal oven and switches that control the tuning operation.

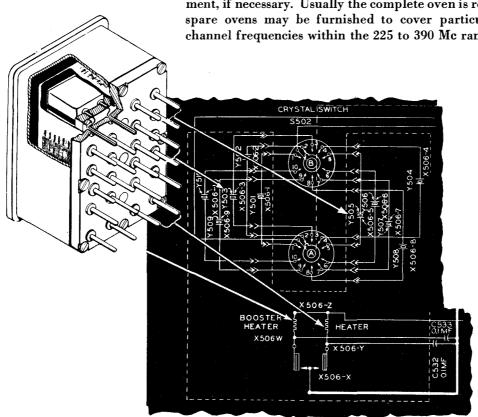

FREQUENCY **DETERMINATION**

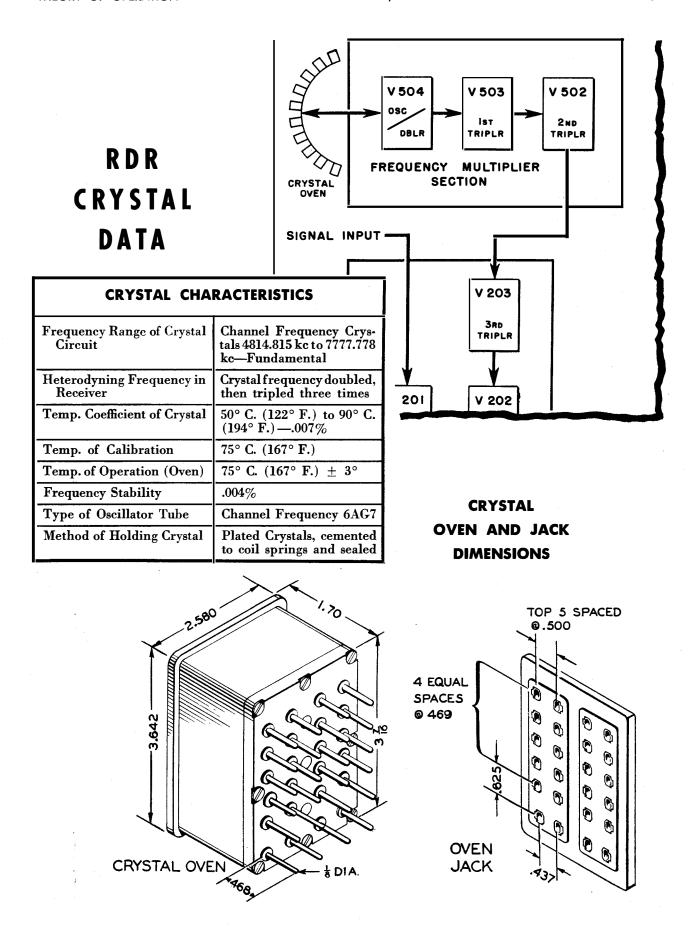

The illustration below shows the details of the switching circuit employed to bring the proper crystal into the oscillator circuit for any given setting of the channel-selector switch. A cutaway view of the crystal oven shows the connection of the crystal holders to the pins protruding from the base of the crystal oven.

Ten pairs of the pins are used to make connection to the ten crystals in the oven. The other four pins serve as terminals for the two heating elements attached to the metal enclosure surrounding the crystal group. The temperature of the oven is controlled by two thermostats in the oven. The space between the metal case over the crystals and the outer case of the oven forms a dead air space to prevent rapid loss of heat from the oven.

The twin-wafer switches S502A and B are mounted behind the jack plate in the receiver selector panel into which the oven is plugged. These switches are driven by the tuning mechanism. The switch blades are rotated by the mechanism when a channel frequency change is being made. Thus, when a tuning cycle is completed, the switches will have brought into the circuit the correct crystal for the selected channel frequency.

The oven can be completely dismantled by removing screws in the base for removal of crystals and individual replacement, if necessary. Usually the complete oven is replaced; and spare ovens may be furnished to cover particular selected channel frequencies within the 225 to 390 Mc range.

RADIO FREQUENCY SECTION

As shown in the illustration of a portion of the

schematic and a simplified schematic, the tuned cir-

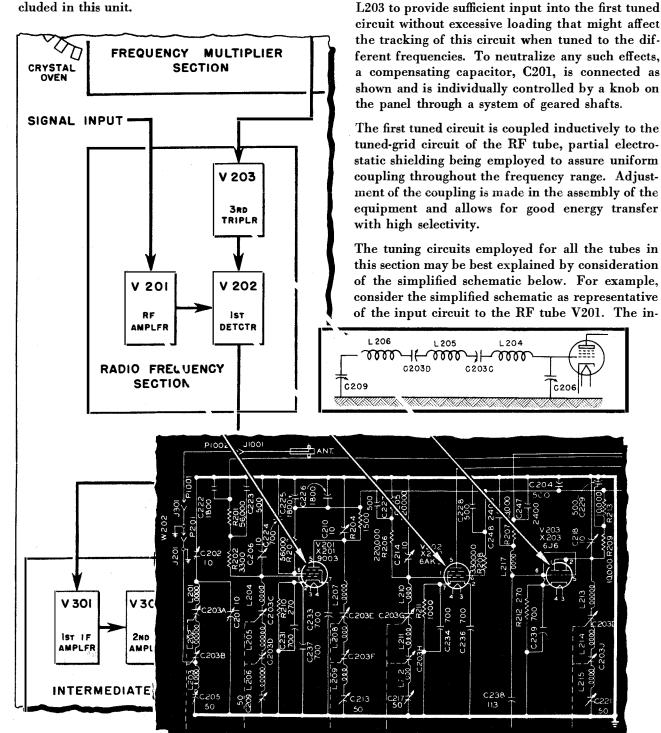

cuits consist of three inductances in series, with

variable capacitors between the sections. Two tuned

circuits precede the RF amplifier tube, V201. The

input from the antenna is tapped into inductance

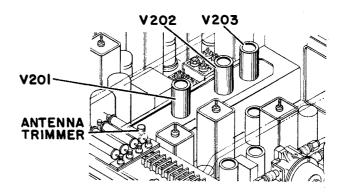

The radio frequency tuning section of the receiver employs five resonant circuits, simultaneously tuned by the RF dial on the selector panel. Four of the circuits are utilized to tune the channel frequency being received, the fifth resonating the output of the heterodyning frequency tripler tube V203 included in this unit.

ductance L204 is of such a value that when the capacitors C203C and C203D are at minimum setting, a resonant half-wave line is formed, with respect to the ground, for the frequencies at the high end of the tuning band. The inductance L205 and L206 have electrical lengths of less than one-half and one-quarter wavelength, respectively, in order to avoid resonance in the tuning band.

As the capacitors C203C and C203D are increased in value, the additional inductances L205 and L206 are gradually introduced into the line. This has the effect of electrically lengthening the line and making it resonant to lower frequencies. Alignment between the tuned circuits is obtained by adjustment of trimming capacitor C206 in the circuit shown, which is connected to L204 at the point of current maximum for the high-frequency end of the band. An additional padder, C209 for the circuit under discussion, is provided for alignment at the point between the middle and the high end of the band.

The output or plate circuit of the RF amplifier is tuned and also coupled inductively to the tuned input circuit of the first detector tube V202.

The output of the second tripler in the frequency-multiplier section is fed to the tripler tube V203 in the RF section. An inductance L217, connected to the grid of the V202 tube, and the coupling capacitor C238 form a filter that assures uniform coupling to the tripler at all frequencies.

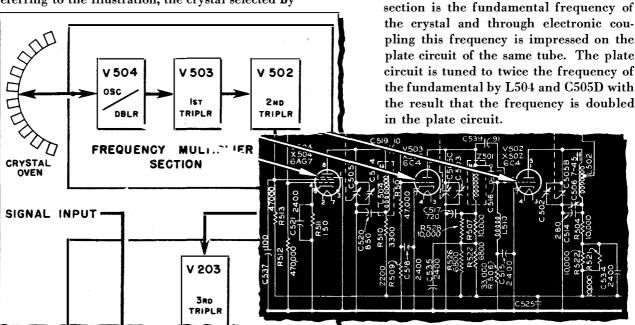

The plate circuit of this heterodyning tripler tube is resonated in the same manner as that employed with the RF tuning circuits and is inductively coupled into the grid circuit of the first detector. A heterodyning action is thus obtained that results in an intermediate frequency of 30.2 megacycles for amplification in the intermediate amplifier.

FREQUENCY MULTIPLIER SECTION

The function of the frequency multiplier, as its name implies, is to develop the necessary heterodyning frequency from the fundamental frequency of the crystals employed with the equipment. Referring to the illustration, the crystal selected by

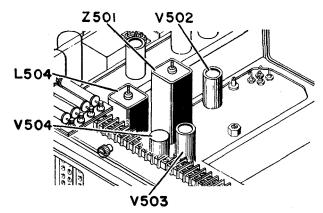

the switching mechanism in any tuning sequence is connected to the grid and screen of the oscillator tube V504 to form a Pierce oscillator.

The frequency generated in the oscillator

The output of V504 is coupled by means of the capacitor C519 to the grid of tube V503. This tube has its plate resonated by Z501 and C505C to three times the input frequency, hence a tripling action takes place to give an output frequency three times that of the input.

In turn, the output of V503 is coupled to the second tripler V502 through capacitor C516 where the tripling action is repeated by the plate circuit of V502 being properly tuned by L502 and C505B. The plate and grid circuits of both triplers are filtered by resistors and capacitors, as shown, to prevent intercoupling or feedback and self-oscillation. A tap is taken on the inductance L502 in the plate circuit of V502 and the output coupled through capacitor C238 to the tripler tube in the RF section, to provide the heterodyning frequency for the receiver.

The four tuned circuits in the frequency multiplier are simultaneously tuned by the Multiplier selector dial on the panel. The circuits are aligned to assure proper tracking at all frequencies by adjustable cores in the shielded tuning inductances and trimming capacitors across the variable capacitors.

INTERMEDIATE FREQUENCY SECTION

The intermediate frequency amplifier consists of four stages of amplification employing fixed tuned transformers Z301, Z302, Z303 and Z304 as coupling between the associated tubes V301, V302, V303 and V304. The transformers are wound with their coupling a little greater than critical, to broaden the top of the resonance curve, and are partially tuned by fixed capacitors connected across the windings, with final alignment being made possible by adjustable cores.

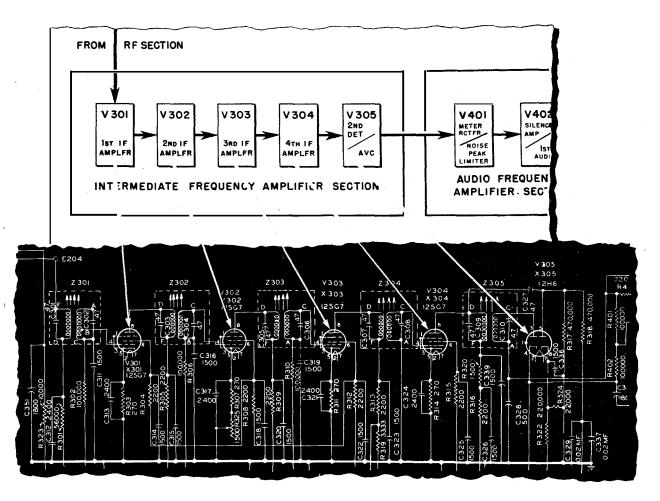

The plate output of the 1st detector is connected directly to the primary of the first intermediate transformer Z301, the secondary being tapped for the input to the first intermediate amplifier tube V301 to obtain better overall stability of the amplifier. The three following stages are identical, particular care having been taken to stabilize the circuits by the use of resistance-capacity filters in the current supply circuits and the use of chokes in the filament circuits. The screen grid potentials of the first three tubes V301, V302, V303 are drawn through resistors in series, with by-pass condensers at points of connection. This method of filtering avoids overall feedback. A variable resistor shown at R325 in the cathode return of the second tube permits the adjustment of the overall response of the intermediate frequency amplifier to the AVC biasing voltages.

The last tube V305 in the section is a double diode. One section is utilized as the second detector; the other section provides automatic volume control. The detector section is connected to the secondary of the last intermediate-frequency transformer Z305, the rectified audio-frequency potentials appearing across the plate-load resistors R401 and R402. The audio-frequency potentials across R401 are then fed to the noise-peak limiting tube V401 in the audio frequency amplifier section and thence to the audio amplifiers.

The right-hand section of V305 is the automatic volume control rectifier that furnishes the bias control voltage for the grids of the tubes to control the gain of the intermediate and radio frequency amplifier stages. Signal input to the AVC section is through capacitor C327 from the plate circuit of the last intermediate frequency amplifier tube.

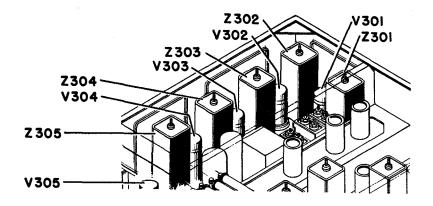

A delay in the action of the AVC circuit is obtained by biasing the cathode of the AVC section of V305 positive by the voltage drop across resistor R324, which is connected in series with the rectifier load resistor R317.

The positive bias is sufficiently great to prevent conduction through the rectifier at signal intensities up to approximately 75 percent of the maximum power capabilities of the amplifier. Beyond this point, the signal input to the AVC section becomes great enough to override the positive bias and the tube conducts current. This current flow results in a potential appearing across R317. The

negative end of the load resistor R317 is connected through R318 to increase the bias voltage applied to the grids of the RF amplifier tube V201 and the first three stages of the intermediate frequency amplifier to reduce their gain.

The circuit values are so proportioned that further increases in signal intensity result in increasingly greater biasing voltage being applied to the grids of the controlled tubes so that the gain falls off more rapidly. This results in a relatively-constant audio output level for wide variations of input. The rapidity of response of the AVC is determined largely by the time constant of the R-C network formed by resistors and capacitors R317, R318, C329, and C337. The time constant is made as small as possible without introducing distortion at low modulation frequencies.

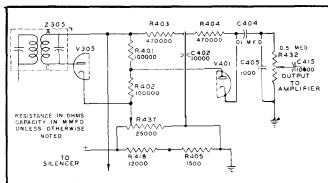

AUDIO FREQUENCY SECTION

In addition to providing the two desired stages of audio frequency amplification, this section includes a noise peak limiter, meter rectifier, and silencer circuit. All these functions are performed by three tubes, shown in the block diagram tied to the schematic to identify the parts and their connections. The lefthand section of the V401 tube is the meter rectifier, used with the meter on the panel.

NOISE PEAK LIMITER—The other diode in the first tube, V401, is used as a noise peak limiter and its functioning may be better understood from the simplified schematic given herewith. The second detector V305 and its load resistors R401 and R402 are shown in the diagram to aid the explanation.

The audio output of the second detector is developed across the load resistors R401 and R402, as previously mentioned. The plate of the limiter section is

biased positive by potential developed across R401 when signals are applied to the second detector, V305, and is thus made conducting. Under this condition the negative audio potentials at the midtap of R401 and R402 can pass through the conducting diode and capacitor C404 to appear as audio-frequency voltage changes across the volume control R432.

SIMPLIFIED SCHEMATIC - NOISE PEAK LIMITER

This condition continues as long as normal signal levels prevail, but a high-level noise impulse will result in a high negative potential appearing at the midtap of the detector load resistors, thus rendering the plate of the diode negative with respect to its cathode and the tube becomes non-conducting. The cathode is held at its normal potential during the plate potential change by virtue of the time constant of the R-C network R403 and C402. With the tube non-conducting, all signal impulses to the output are cut off, with the result that the noise peak is barred from the amplifiers. On cessation of the noise impulse, the circuits return to their previous condition and the normal signals may pass

Output to the audio amplifiers is controlled by the setting of the output level control R432 which determines the output of the receiver. A capacitor C405, connected across the output level control potentiometer R432, is intended to by-pass the higherfrequency audio currents to reduce hiss in the audio output.

through the tube to the audio amplifiers.

SILENCER—The second tube, V402, in the audio amplifier section is a double triode and functions both as silencer amplifier and first audio amplifier. The output of the noise-peak limiter V401 is coupled to the grid of the right-hand section of V402 by means of capacitor C415, as shown in the simplified schematic, which, for ease of explanation, also includes the detector plate load resistors R401 and R402.

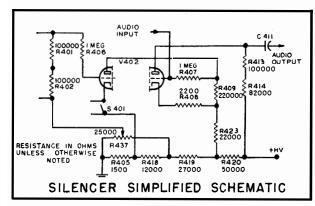

IOISE PEAK LIMITER

Plate current of the audio amplifier section of V402 flows through R413 and R414, which act as the plate load for the tube. Variations of plate current due to received signals appear as voltage changes across these resistors. These potentials are coupled through C411 to the audio output stage V403.

Normal grid bias for the audio amplifier is obtained from R408, connecting through R423 to voltagedropping resistors. However, R409 is included in the grid circuit of the audio amplifier and in the plate circuit of the left-hand or silencer-amplifying section of the tube.

SILENCER AMPLIFIER

The silencer amplifier grid is connected across the output of the second detector as shown. The grid of the silencer amplifier, if biased positive by the variable resistor R437, permits current to flow in the plate circuit. This results in a voltage appearing across R409 that biases the audio amplifier grid beyond the cutoff point and renders the tube inoperative. Thus, no sound is heard in the output of the receiver.

Should a signal of sufficient intensity reach the output of the detector to override the positive bias on the grid of the silencer amplifier, the grid would become negative, cutting off the plate current. With the reduction of plate current, the biasing voltage across R409 would decrease and allow the audio amplifier to function normally. When the signals cease, the silencer amplifier grid would become positive, allow the plate current to flow again, and bias the audio amplifier to the cutoff point. This renders the receiver silent between signals.

SILENCE LEVEL CONTROL

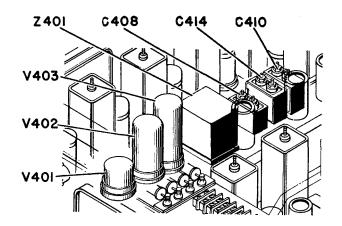

The Silencer control setting on the panel determines the point at which signals can pass through; hence, the control should not be set higher than will permit the weakest signal received to override the positive bias on the amplifier and be heard. A switch, S401, is provided on the panel to render the circuit inactive. No plate current can flow in the silencer amplifier section when this switch is opened.

One pair of contacts on the relay K602

is connected across the Silencer switch S401. This relay may be operated from a remote position to which the output of the receiver is connected and the silencer circuit can thus be switched off V 305 V401 V402 V403 by remote control. 2nd METER SILENCR AUDIO NOISE OUTPUT AUDIO FREQUENCY SECTION AMPLIFIER SECTION AUDIO OUTPUT 220000 4700 SILENCER LEVEL

AUDIO OUTPUT—The output of the first audio amplifier tube V402 is coupled by capacitor C411 into the grid circuit of the audio output stage V403. A capacitor C413 is connected across the input to this tube to bypass the higher-frequency components of the audio currents.

A filter and coupling network Z401 is connected into the plate circuit of the output tube. From the impedance in the plate of the tube, the audio output is coupled to the audio-frequency band-pass filter in the network of Z401. This network passes frequencies between 300 and 3000 cycles to an RF filter Z402 and thence to the local headset jack associated with the filter. The RF filter is used to prevent radio frequency currents picked up by the headset cord from entering the equipment at this point and setting up disturbances in the receiver.

The output of the receiver may be fed to a remote position by connecting a cable to the output receptacle Z603.

AUTOMATIC TUNING MECHANISM

The tuning of the receiver to the ten preset channel frequencies is accomplished by two compact selector mechanisms, one to adjust the R-F section, the other the multiplier. The selectors are geared to a motor which is controlled by a system of switches and relays. The electrical circuits employed with the motor are shown in the illustration, including the relay K602 for the remote control of the silencer circuit. The functioning of the electrical components of the automatic tuning assembly shall be considered first.

The channel-selecting switch, S601B, is operated by a knob on the panel and is used to select the channel frequency desired. It will be noted that this switch has 11 contacts and when placed in the position 1, marked Remote on the panel, transfers control of the mechanism to a similar selector switch that may be connected to the terminals on the terminal board E106. The other ten positions of the frequency switch, S601B, are for controlling the tuning mechanism.

A similar wafer switch, S601A, is mechanically-connected to the gear train through an idle selector drum and will rotate in only one direction. This switch is of the closed-circuit type, the rotor contacting all but one of the fixed contacts in any given position, while the selector switch S601B is of the open-circuit type, the rotor contacting but one fixed contact at any time.

A limit switch S603 is actuated by a cam driven by the gear train and is in the open position when the mechanism is at rest, that is, with the equipment tuned to a given frequency.

When a change of frequency is to be made, the selector switch S601B is moved to a point corresponding to the frequency desired. This will close the circuit from the negative bias lead, through relay coil of K601, the homing switch, and then to ground.

The relay closes contacts 4 and 3 to complete the circuit through one field and the armature of the motor, to cause it to run in the counter-clockwise direction. The motor will drive the selector mechanism, rotating the cam to allow the limit switch to close, and the homing switch, until the latter switch reaches the point where its rotor position corresponds to that of the selector switch. The circuit to the relay will be opened by the homing switch and the relay armature allowed to drop back. This action has advanced the slotted drums of the selectors to the proper position for the frequency desired.

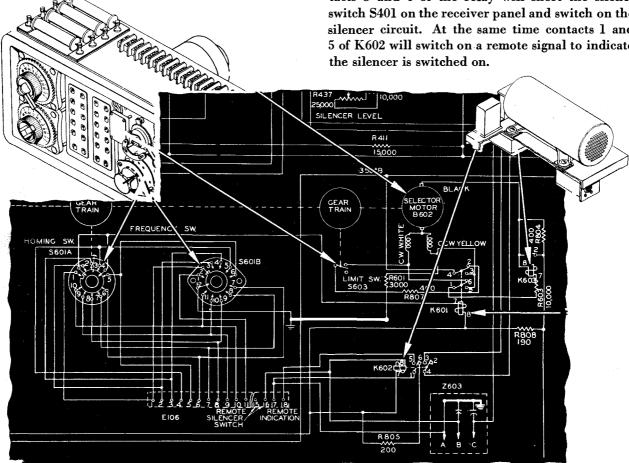

The relay armature, on release, closes contacts 4 and 2 and current flows through the closed limit switch to the other field of the motor. The motor reverses its direction, the selector drums remain properly positioned, but the shafts of the tunable elements are rotated until they are locked in their proper position by pawls. At this point, a slipping clutch permits the motor to continue running until the cam opens the limit switch and stops the motor in its original position. This completes the tuning cycle.

It will be noted that the relay K601 carries a second set of contacts, the moving contact 1 acting to connect the coil of voltage-regulating relay K603 across the motor terminals when the motor is operating, by means of contacts 5 and 6. The contacts of relay K603 are connected across a resistor R804 in the motor lead. This combination acts as a voltage regulator on the motor, to compensate for any change in output voltage of the dynamotor. The relay contacts are normally closed but are held open when the motor is switched on and resistor R804 is in the circuit. Should the voltage across the motor terminals drop below 120 volts, the relay armature will drop back and short out the resistor to increase the voltage to the motor. Should the voltage exceed 160 volts, the relay armature will be pulled up and the resistor R804 placed in the circuit. This control keeps the motor voltage between 120 and 160 volts to assure proper functioning of the motor.

The resistor R601 performs an important function in this circuit. The voltage for the operation of relay K601 is obtained across the bias resistor R805 in the negative lead of the high-voltage output of

the dynamotor as shown in the overall schematic diagram. This voltage is dependent upon the load drawn by the receiver tube circuits. When the selector motor is in operation, any drop in voltage due to the motor load will be reflected in a drop in current drawn by the receiver. In turn this will reduce the voltage drop across the bias resistor R805, possibly to the point where relay K601 would fail to function. To prevent this, the resistor R601 is in the circuit at such times as the motor is running with the relay energized and current is drawn through this resistor to ground, that must flow through resistor R805 to the negative terminal of the dynamotor. In this manner the current through, and consequently the voltage drop across R805 is maintained at the proper value to operate the relay

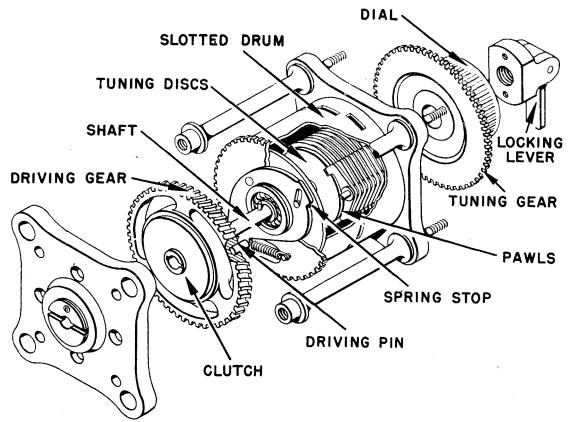

The coil of the silencer control relay K602 is connected to both the terminal board E106, for leads to the remote frequency selector switch and to the remote connector of the receiver, Z603. A remote switch arranged to short terminals 16 and 17 of the terminal board or to close the circuit of A and B of the connector will cause the relay to close. Contacts 3 and 4 of the relay will short the silence switch S401 on the receiver panel and switch on the silencer circuit. At the same time contacts 1 and 5 of K602 will switch on a remote signal to indicate the silencer is switched on

An unusual circuit is employed to assure sufficient current to energize the relay K602 and maintain a constant negative bias. It will be noted that with the relay in its normal position contacts I and 6 are closed, to ground the bias resistor R805 that provides the -20 bias voltage used in the receiver circuits. When relay K602 is energized, by closing of the circuit between terminals 16 and 17 of terminal board E106 or leads to contacts A and B of receptacle Z603, contacts 1 and 6 are opened, disconnecting R805 from the ground connection. How-

ever, the closing of the circuit to the coil of the relay through contacts 1 and 5 has connected the relay winding between the negative lead of the dynamotor and the ground. The resistance of the relay winding has been so chosen that when the contacts 1 and 6 open, the relay winding is acting as the bias resistor instead of R805 as long as the relay remains energized. This circuit prevents the reduction in negative bias to the receiver that would result if the relay winding were simply connected across the bias resistor R805.

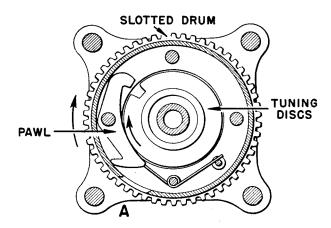

FUNCTIONING OF TUNING SELECTORS

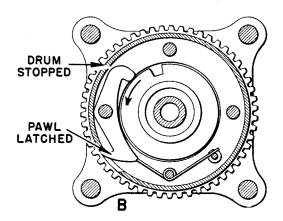

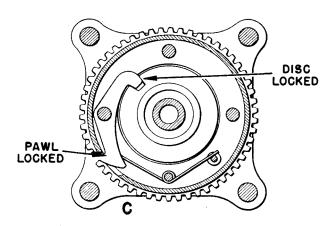

The tuning selectors are compact mechanical devices that consist essentially of an outer drum with ten slots, equally staggered diagonally around the drum. Within the drum, and pivoted on a post extending from the front plate of the selector, are a series of ten spring-actuated pawls. As the drum revolves, each slot in turn passes over its respective pawl, the end of each pawl being forced into the slot by a spring, but continued rotation of the drum forces the pawl free of the slot.

In the center of the drum, and spaced on the shaft connecting to the tunable element, is a series of ten notched discs. These discs are clamped tightly to the shaft by a cam and lever locking arrangement attached to the selector knob, but can be released by raising the lever on the knob, so any disc can be adjusted in relation to the shaft, independent of the others.

The shaft and discs are driven by a friction clutch mounted in the large gear at the rear end of the selector, the end opposite to the dial. The tension on this clutch is sufficient to drive the shaft in either

direction unless the shaft is locked by the action of the pawls engaging the notches in the discs. The drum is driven by a pin in the large gear engaging a spring stop on the end of drum, arranged to drive the drum in one direction, that is, only when the motor is running forward in the first part of the tuning cycle. The relative positions of the drum, pawls, discs, and gear are shown in the illustration and the sequence of operation is as follows.

When the motor is energized, the worm gear of the gear train drives the large gear, which in turn rotates both the drum, by means of the pin and stop, and the shaft and grouped discs, through the clutch action. This action is shown at A in the illustration, the direction of rotation of the parts being indicated by arrows. The slots in the drum ride over the free ends of the pawls.

When the drum has reached its proper position, as determined by the homing switch opening the relay circuit, the motor will stop. The end of a pawl will extend into its associated slot in the drum.

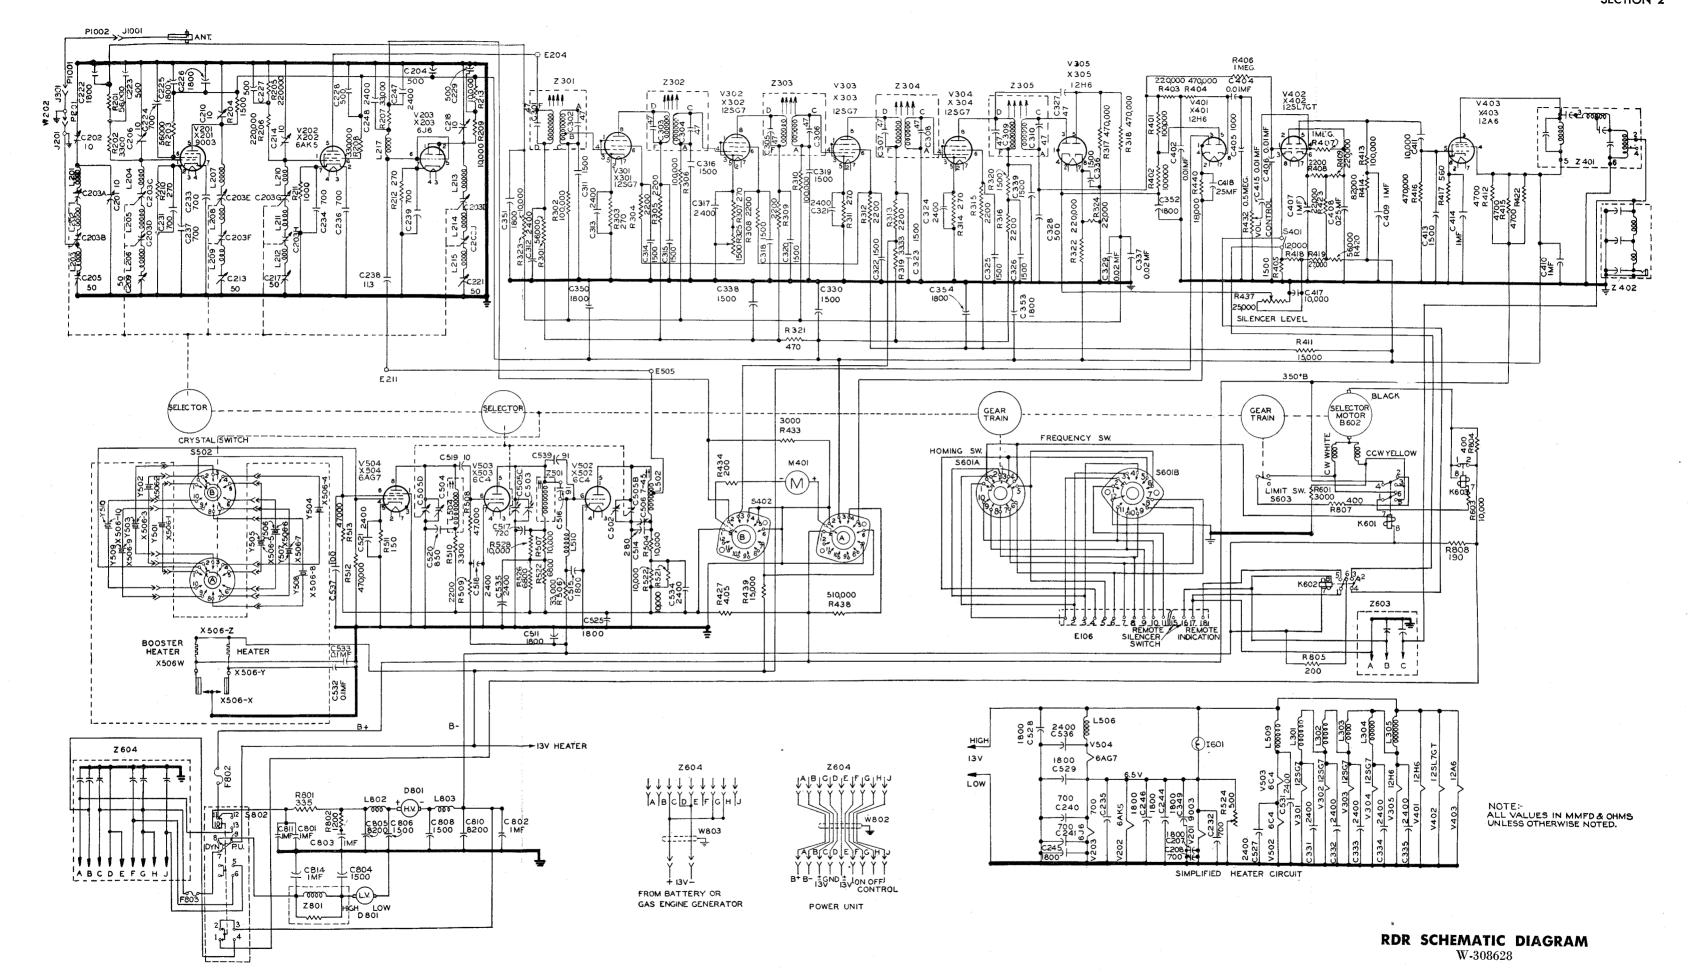

As the motor is reversed by the relay contacts and the gear of the selector turns back, the drum retains its position as the hook end of the pawl engages the end of the slot as shown at B in the illustration. The inner end of the pawl is now contacting the edge of its associated disc on the shaft. The shaft and discs are turning back with the motor because of the clutch drive, as indicated by the arrows. This continues till the notch in the disc comes under the cocked pawl. As the pawl drops into the notch the free end of the pawl extends further through the slot in the drum and rotation of the discs and shaft are stopped as shown at C. The gear drive continues, but the clutch comes into play and allows the shaft of the tunable element to remain fixed in position as the motor operates until stopped by the action of the limit switch. The tuned element is now properly adjusted to the frequency for which it was pre-set.

The above tuning cycle is repeated for each change of frequency. A pair of wafer switches S502A and B are geared to mechanism so the proper crystal is connected into the circuit of the oscillator for each frequency as selected.

When the next change of frequency is made the large gear will rotate alone until the pin on the gear engages the spring stop on the drum. The drum is then revolved and in so doing, unlocks the pawl by forcing in the free end extending through the slot in the drum, and disengages the pawl from the notch in the disc. This allows the discs and shaft to turn with the drum until the drum reaches the position required for the new frequency. The reversal of the motor again causes discs and shaft to revolve until stopped by the pawl engaging a notch in a disc.

INSTALLING RDR RECEIVER

The RDR receiver in conjunction with a power supply forms a complete operational unit and may be used independent of other radio equipment. However, it is usually installed in connection with MAR equipment as a companion receiver.

When the RDR receiver is to be used with the MAR, the usual practice is to make provision for its mounting when installing the support frames for the MAR equipment. Where the RDR receiver is to be used alone in a permanent installation, some form of support will have to be provided.

Typical installations of the RDR receiver are shown on the opposite page in connection with MAR equipment. As will be seen, two frames have been provided for the combined shipboard installation. The frames may vary widely in detail in different installations but must possess in common the factors of extreme rigidity and freedom from resonant or vibrating members in their construction.

The frame shown in the illustration, typical of those that may be employed for the purpose, is fabricated from channel and angle irons welded together to form a rigid form to which the bases of the shockmounts are bolted. Where it is intended that the RDR be used, two such frames are erected, one

above the other or both on the same level. The grouping of the equipment will then depend upon which arrangement is employed.

Where the two frames are arranged one above the other, as shown in the illustration of a typical installation, the lower frame supports the modulator-dynamotor and power supply unit of the MAR equipment. The upper frame has the transmitter-receiver suspended under it, providing on top, room for mounting the RDR.

In the alternate system of grouping, where the frames are on the same level, the assembly will differ somewhat because of limitations imposed by the cables interconecting the MAR equipment. The MAR transmitter-receiver and modulator-dynamotor are paired and attached to one frame. The other frame will then support the power unit in a suspended position, with the RDR receiver mounted on top.

The shockmount assembly for mounting the receiver is furnished with the MAR shipboard installation kit. The Navy type CRV-10508 is used with the receiver and provides the correct suspension for this unit.

ATTACHING THE SHOCKMOUNTS

NAVY TYPE CRV-10508

The first procedure, after removing the RDR receiver from its shipping container is to attach the shockmount to the receiver case. The mount is to be attached to the bottom of the receiver, which can be determined from the position of the carrying handles on the ends of the case without removing the cover. There is less likelihood of damaging the equipment if the shockmount is attached before removing cover from the case.

Loosen the clamping screws on the front of the shockmount and slide the top frame off the base member. Untie the small canvas bag and dismantle the frame section by removing the short carriage bolts from the sides of the frame and the long carriage bolts through the rear shockmount units and slides. This leaves the frame and slides held together by the two hex head bolts through the front shockmount units.

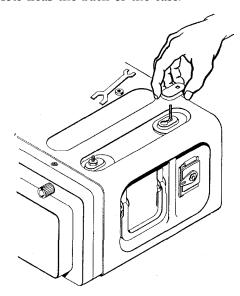

The case is then prepared for receiving the mount by fastening the four carriage bolts into the keyhole slots on the side of the case to which the mount is to be attached. To attach the bolts, lay the case on its side, insert the head of a short carriage bolt in the keyhole slot nearest the cover of the equipment, and slide the bolt to the end of the square slot. Drop one of the saddles provided over the bolt shank with flanges down and screw a large nut, with the counterbored side down, onto the bolt threads. Tighten with open end wrench attached to the base.

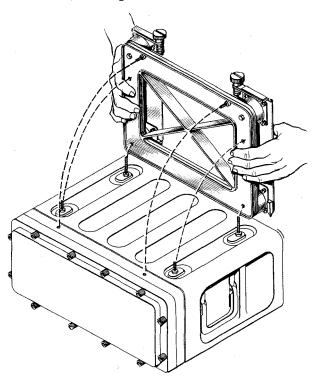

COMPONENTS OF SHOCKMOUNT ASSEMBLY

QUAN.	PART	QUAN.	PART
2	Carriage bolt 5/16 x 25/16	2	Carriage bolt 5/16 x 1½
4	Hex nut (large)	4	Saddle
1	Frame	2	Hex Hd. machine bolt
4	Shockmount for CRV-10508	2	Washer
2	Capscrews	6	Lockwasher
1	Base (Assembly)	1	Slide assembly (left)
6	Hex Nut (small)	1	Slide assembly (right)
1.	Wrench	6	Lockwasher 5/16

Follow the same procedure as shown in the illustration in attaching the long carriage bolts in the keyhole slots near the back of the case.

To attach base and slides to the case, insert the two hex head bolts with washers and lockwashers, that were in the small canvas bag attached to the shockmount, into the two holes in the front edge of the frame. Grip the frame and slides as shown in the illustration, holding the holes in the shockmounts

on the slides in line with the holes in the frame, and place the assembly on top of the bolt ends in the case, entering the bolts into the holes indicated. Lockwashers are placed on the four carriage bolts and nuts started on the bolt threads. The capscrews can then be started into the two matching tapped holes in the case.

All six nuts and the two capscrews may now be tightened with the wrench. These consist of the four nuts on the carriage bolts, the two nuts on the bolts through the front shockmounts and the two capscrews. This completes the attaching of the shockmounts, and the unit is ready for installation.

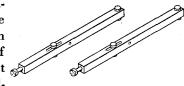

The base section of the shockmount is bolted to the support frame by bolts through the eight holes in the base and holes in the frame. Should the holes in the frame be tapped, only capscrews will be required to hold the base of the shockmount in place. Use lockwashers under the nuts on the bolts or heads of the capscrews, for the base assembly must be rigidly attached to the support.

The receiver can now be slid into place on the base member of the shockmount. Slides on the unit are engaged with the slide members attached to the base and the unit pushed into place. Conical pins at the rear end of the slides will engage in holes in the angle plate at the rear of the base. The clamping screws on the front of the slides are started into the tapped posts at the front of the base and tightened to lock the unit rigidly to the base.

ATTACHING CABINET FASTENERS

NAVY TYPE CRV-10505

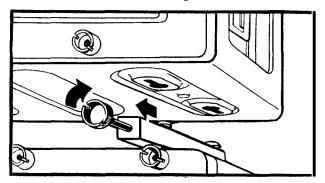

For certain applications, as when the RDR is used with field installations of the MAR, cabinet fasteners are provid-

ed with the MAR equipment that may be used for clamping the receiver to the MAR equipment or to the accessory box furnished with MAR.

The fasteners are installed between the stacked cases and are provided with button headed sliding members that can be engaged in the keyhole slots in the cases and tightened from the front, to lock

the assembly together. Such assemblies should only be made when the equipment is not subject to the shock and vibration of moving vehicles or craft.

The fasteners are installed by first sliding the knob at the end of the fastener out to the extreme length of its sliding stem. Then rotate knob to the left, causing the button members to move to such a point that they fit freely into the holes in two of the keyhole slots in the side of the equipment cases.

Two fasteners are placed in the holes in the top of one of the equipment cases and the RDR receiver is then lifted on top of the fasteners with the holes in the keyhole slots engaging the button heads. The knob on the front of the fastener is then turned to the right, as shown in the illustration, to clamp both units rigidly together.

INTERCONNECTING RDR RECEIVER

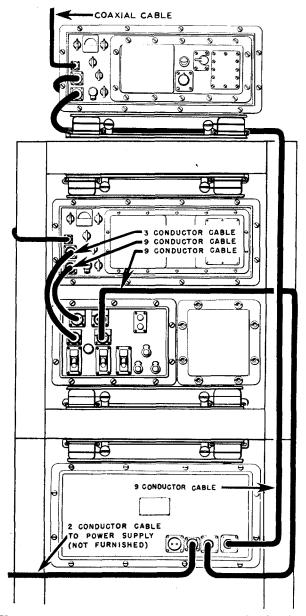

WITH MAR EQUIPMENT

Remove the cover of the receiver by loosening the thumbscrews along edge of cover using either the allen wrench or wide blade of the screwdriver clipped to the ends of the case. Removal of the cover will expose the operating panel of the receiver, which should be carefully examined for broken or loose fittings or controls.

The accessory box, with the receiver, contains two cables for connecting the receiver to the power supply and a battery cable fitted with clips. The eight foot, nine conductor cable is for connecting the receiver to the power supply unit used with the MAR equipment. The short cable is an adaptor cable, intended to adapt the nine contact input power jack on the receiver to a two wire cable, when the source of power for the equipment is 13V direct current from storage batteries or a gas engine driven generator source.

The method of connecting the RDR to the power unit is shown in the illustration. Make sure all power switches are set on the Off position before attempting to connect these cables.

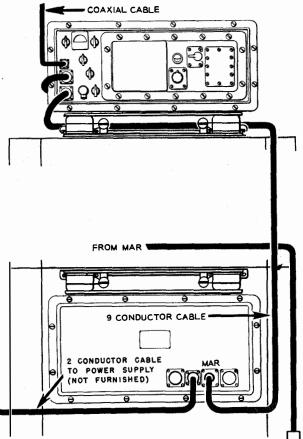

The longer nine conductor cable has one end connected to the power input receptacle on the receiver by removing the cap from the receptacle, inserting the plug on the cable into the receptacle and tightening the retaining ring on the plug onto the threaded shell of the receptacle.

The cable may be run by any convenient path through the MAR assembly and the other end of the cable connected to the extreme right hand output receptacle of the power unit. This is the normal connection when the RDR receiver is operated from the power supply unit in conjunction with the MAR.

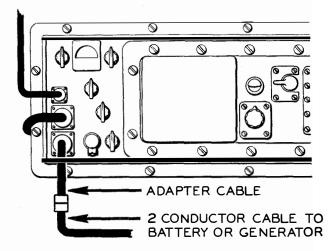

With this connection, the MAR power switch controls the power supply unit, switching it on and off as necessary. The power switch on the RDR serves only to cut this unit off when not required, but this switch does not shut off the power unit. Thus the MAR must be switched on before the RDR can be put into operation. The relay controlling the power unit is connected only to the receptacle to which the MAR is connected.

However, should it be necessary to operate the RDR receiver from the power unit without the MAR, the cable from the RDR should be connected to the second receptacle from the right, marked MAR as shown in the illustration below. This connects the power switch in the RDR to the relay circuits in the power unit and when the RDR power switch is moved to the P. U. position, the power unit will be switched on.

As previously mentioned, the short cable is intended as an adaptor cable and is fitted with a nine terminal plug at one end and a two terminal jack at the other. When the RDR receiver is operated from a 13V direct current supply, the nine terminal plug of the adaptor cable is attached to the power input receptacle on the RDR panel. The cable from battery or generator can then be connected to the jack on the adaptor cable.

The cable used for connecting the adaptor cable on the receiver to a battery, as in the case of mobile

units, is fitted at one end with clips. In connecting this cable to the batteries it is important that the black sheathed clip be connected to the grounded side of the battery in the vehicle. The red sheathed clip is connected to the ungrounded side of the battery. The fact that so connecting the clips may reverse the polarity in a given installation does not affect the operation of the receiver.

A twenty five foot cable is furnished with the gas engine driven generator for connection between adaptor cable and generator. One end of this cable is plugged into either receptacle on the generator control box and the other connected to the adaptor cable. With this arrangement it is also possible to connect a storage battery to the generator unit by means of the battery cable, as stand-by.

The power switch on the RDR receiver must be moved to the Dyn. position to switch on the receiver when the adaptor cable is used. The dynamotor in the receiver is put into operation with the low voltage supply to provide necessary plate voltage for the tubes in the receiver.

INSTALLING THE ANTENNA

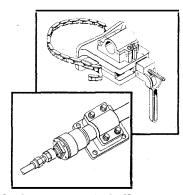

When used with the MAR equipment, the antenna for the RDR receiver should be installed at least ten feet from the MAR antenna. It should be erected in as clear a space as possible and at least $1\frac{1}{2}$ feet from any conducting objects.

The antenna carrying case contains the antenna and accessories, including a ten foot coaxial transmission line assembly fitted with connectors. A fifty foot transmission line assembly and connector are included in the equipment accessories chest.

The antenna is furnished dismantled, but requires only that the two rods be installed, to fit it for use. A wrench is provided for making this assembly.

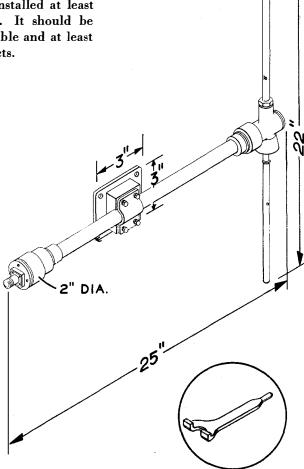

Remove the antenna body from the case and screw the threaded ends of the rods into the tapped holes provided. The hole in the casting for mounting the ground rod has a coarse thread, the other hole, in the stud in the molded insulator, has a finer thread. The rods have different threads and will only fit into their proper mounting holes. The small end of the wrench is inserted in holes in the rods to tighten them till they bottom in the holes. The other end of the wrench is intended to tighten the locknuts on the rods to prevent their working loose and falling off.

The first step in installing the antenna is to mount the antenna clamp on the intended antenna support. If the shipboard clamp is to be installed, remove the clamp from the antenna body by loosening the four capscrews holding the

cap over the tubular body section. A drilling pattern is shown in the illustration, it being possible to attach the clamp to either borizontal or vertical surface.

With the clamp in place, the tubular body of the antenna is inserted in the curved recess in the clamp with the end of the antenna mounting the

transmission line connector adjacent to the clamp. Replace the cap on the clamp and start the four capscrews into place. Rotate the antenna body till the insulated rod is pointing down and tighten the capscrews to hold the cap and antenna firmly in position.

The procedure is the same with the chain clamp. First attach the clamp to the support, then loosen the wing nut holding the hinged cap intended to grip the antenna body. Swing the clip out of the way, insert the antenna in the curved depression in the clamp and swing the clip back over the antenna body. The wing nut is then tightened onto the clip when the antenna radiating rods are in a vertical place with the insulated rod pointing down.

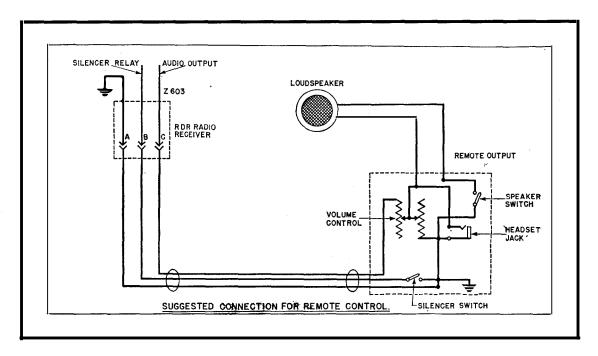

INSTALLING THE TRANSMISSION LINE

A 10 foot coaxial cable, fitted with plugs, that connect to the antenna and receiver receptacles, is included with the antenna. In some installations it may be possible to use this cable for connecting the antenna to the receiver. In this case it is a simple matter to unscrew threaded plugs from the retaining rings of the cable and, after removing the cap from the antenna receptacle on the receiver, insert the cable plug into receiver receptacle and tighten retaining ring. At the antenna end, the connection is made in the same manner to the receptacle on the antenna body but no part of the transmission

line should run parallel to the dipole rods within a distance of five feet.

Where a longer transmission line is required, a 50 foot coaxial cable fitted with plugs and a connector are furnished with the accessories. This cable is installed by simply plugging into antenna receptacle and receptacle on receiver panel as in the case of the 10 foot transmission line. By utilizing the connector it is possible to join the two transmission lines together to obtain an overall length of 60 feet.

REMOTE OUTPUT

A receptacle is provided on the panel of the receiver for connecting the audio output of the receiver to a loudspeaker or headset at a remote location. A three terminal plug is furnished among the accessories for attaching to the end of a three conductor cable that is used for making the connections to the remote installation. For guidance in making the connections, a suggested system of wiring is shown in the illustration when equipment is available for the purpose.

As will be seen, the reproducer, which may be a loudspeaker or headset, and control are connected to terminals 1 and 2 at the remote end of the cable. A switch is connected across terminals 2 and 3. The speaker may be switched on or off as desired and the volume regulated to suit conditions. The other switch controls the silencer circuit; opening it cuts off the silencer when signals are to be received that are too weak to override the degree of silencer action being employed at the receiver.

SETTING UP ENGINE DRIVEN GENERATOR

Remove the metal case containing engine driven unit from luggage type shipping case and loosen thumbscrews holding cover on case. Withdraw the unit completely from case after removing cover and place on fairly level space within a 25 foot radius of the radio equipment.

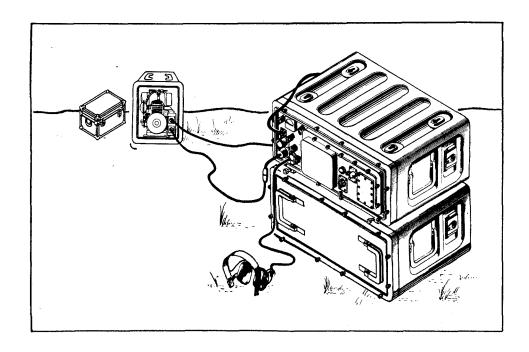

The cable to connect generator unit to radio equipment is removed from luggage case. Connect one end of the cable to one of the receptacles located on the control box next to the generator. The other end of the cable is plugged into the two connector receptacle on the adaptor cable attached to the receiver. Make sure the power switch on the radio equipment is in the OFF position and the switch on the control box on the generator unit is in the RADIO position.

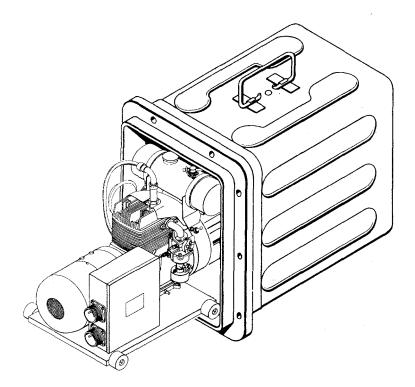

The engine should have all moisture-proofing removed. This is important to be sure all openings on carburetor, oil breather, fuel tank vent and generator ventilation will be free of obstruction.

The crankcase of the engine should be filled, to the level of the plug on the side of the crankcase of the engine, with the proper grade of engine oil. For normal operating conditions Navy symbol No. 2190 or No. 2135 grade oil should be used. Oils heavier than S.A.E. 20 should not be used. The capacity of the crankcase is one pint.

The fuel tank is to be filled with clean gasoline, high test preferred. The engine will operate satisfactorily on gasolines having an octane rating from 68 to 100, either leaded or unleaded. Use a clean container and funnel for filling. The fuel tank air vent should be unscrewed from the top of the tank and replaced in the vertical or open position. Make sure the air cleaner on the carburetor is in place and free of all moisture-proof packing material.

Open fuel line valve at bottom of fuel tank and remove plug in breather pipe on crankcase and the engine is ready to start.

Place ignition switch, located on flywheel housing, in the ON position and close the carburetor choke located on lower portion of carburetor above the air filter. Wrap the starter rope around the grooved pulley on the engine in a clockwise direction. Steady the engine with the left hand and exert a quick pull on the rope to spin the engine. If the engine fires, open choke valve at once unless the surrounding temperature is very low when the choke may be left partially closed to permit engine to warm up.

If the engine does not start, open choke valve and repeat rope pull operation until the engine starts. Should the engine fail to start after several attempts with the choke open, the above operation should be repeated, closing the choke for one pull of the starter rope and opening the choke for several pulls. Do not attempt to adjust needle valve on carburetor during the starting operation as this adjustment has been made at the factory.

The engine should start after a few pulls on the starter rope and failure to do so after a reasonable number of trials indicates some fault in the preparations or damage to the engine. Reviewing sec-

tion 7 covering engine faults will assist in locating the trouble.

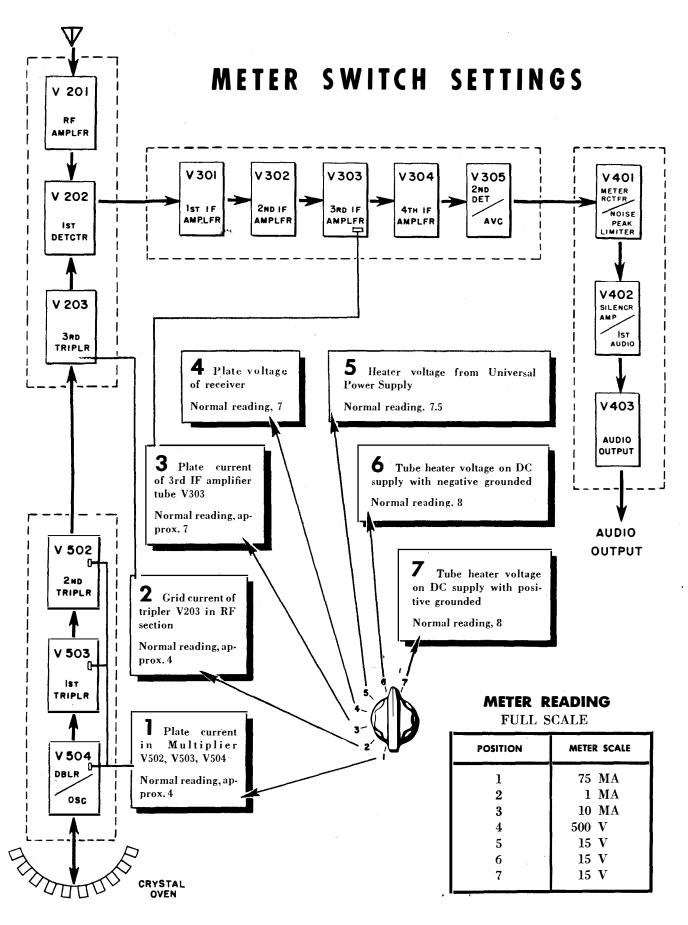

After the engine has started allow it to warm up for five minutes before placing a load on the generator, after which the operation of the radio equipment may be checked.

In sub zero weather special precautions must be taken or poor operation of the engine will result which may cause damage to the engine or complete failure.

Winter type high vapor pressure gasoline must be used in the fuel tank.

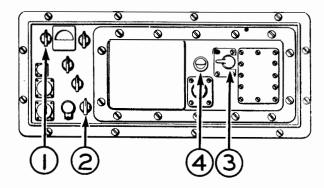

Oil that flows freely at —40 degrees F. must be used to prevent damage to the engine while warming up. In case low temperature oil is not available, No. 10W oil may be diluted with wax free kerosene in a proportion roughly equal to the temperature. Thus at —30 degrees F. add 30% kerosene and at —40 degrees F. add 40% kerosene.

If possible, warm the engine with a blow torch before starting, which assures proper lubrication immediately, and protect it from direct air blast while warming up or if operating on light load.

CHECKING THE RECEIVER

The receiver is shipped with the tuning selectors adjusted to signal frequencies as determined by the characteristics of the crystals in the crystal oven. All tubes are in place and after the receiver is installed and connections made it should be ready for operation.

To check the receiver, place the Output Level (1) on O and Silencer switch (2) on OFF. The power switch (3) may then be turned to the proper position to switch the equipment on, down to the Dyn. position when 13V direct current is used as power supply or up to the PU position when the equipment is using the power unit. Make sure the MAR Power switch is in the ON position if this equipment is being used with the RDR. The panel light (4) should glow. Rotate cap on top of light shield to make sure the light aperture is opened. It is important that this light be on; should it be defective it will unbalance the heater circuit voltages.

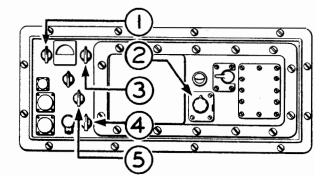

Allow the tubes to heat for a few minutes, then check the heater voltage by means of the meter on the panel. Place the meter selector switch on position 6 when 13V direct current is being used with the negative grounded. A meter reading of 8 should result. Should a higher or lower reading be obtained, check voltage of power supply.

Where the positive side of the direct current supply is grounded it will be necessary to use position 7 of the meter switch to obtain a meter reading.

When the power unit is used as power source, meter readings to check the heater voltage are taken on position 5 of the meter switch. The high voltage supply to the tube plates is then checked by placing meter switch on position 4 which should give a reading of 7.5.

Insert headset and extension cord into the phone jack on the panel and turn the Output Level control to the right to bring up the background noise. Should the background noise not be heard, it is reasonably certain that a tube has been damaged and should be replaced.

Having turned up the Output Level control (1) and obtained background noise, check the operation of the automatic tuning mechanism by rotating the channel selector switch (2) to each channel in turn, endeavoring to pick up signals. When signals are received, they may be sharply tuned in

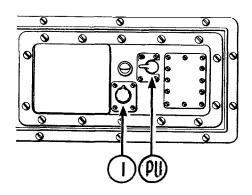

with the Antenna compensator knob (3) on the panel. The Silencer switch (4) can be moved to ON and the Silencer control (5) gradually turned to the right to reduce the background noise. With signals of sufficient intensity the background noise may be removed entirely during no signal periods. However, the Silencer control should not be set so high as to cut off the weakest signals to be received.

Should it be impossible to pick up signals or background noise, and tubes are known to be in operating condition, it may be necessary to retune the receiver.

ADJUSTING THE RECEIVER

The receiver is tuned and adjusted after assembly, and the equipment is shipped ready for operation with tubes and crystal oven in place. The following instructions will only apply should the settings of the selector dials become disturbed due to replacement of parts or change of crystal oven.

With the receiver connected to power supply and antenna, rotate the channel selector switch to position I and switch power on the receiver. Proceed to remove the panel covering the selector dials and crystal oven by loosening the screws around the edge of the panel. As the panel is removed it will be noted the knobs and panel light reflector remain on the panel. Mechanical coupling devices between the knobs and their respective controlled units make it unnecessary to dismount the knobs from their shafts when removing the panel. The selector dials are in position for adjustment to the first channel frequency.

- 4
- 1. Output level at 5 or 6
- 2. Silencer level at 0
- 3. Plug headset into jack on panel

TUNING SEQUENCE

- 4. Rotate meter switch to position 1.
- 5. Unlock the Multiplier dial by swinging lever on dial until it stands straight out from dial knob. Insert vernier knob into hole adjacent to dial and rotate the dial slowly until a reading of 5 to 7 is obtained on the panel meter. Leave the dial at this setting but do not lock.

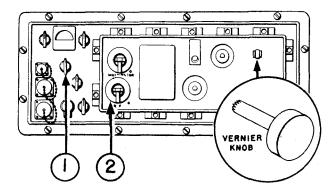

Rotate meter switch to position 2 to check grid excitation on the last tripler of the heterodyning frequency multiplying stages. Readjust the setting of the multiplier dial slightly to obtain a maximum reading of not less than 4.1 on the meter. Then de-

press the lever to lock the dial without disturbing the setting.

The meter selector switch (1) is now moved to position 3 and the locking lever on the R-F selector dial (2) raised.

The R-F dial is slowly rotated by means of the vernier knob and as the correct setting is approached there should be a marked increase in the background noise in the headset and a decrease in the meter reading. When maximum background noise is heard, readjusting Output level if necessary for comfort, and minimum meter reading obtained, lock the dial by depressing lever. Do not disturb dial setting while locking.

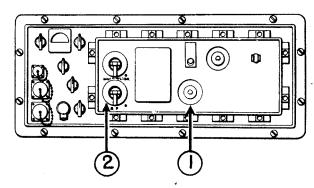

The receiver is now tuned to the first channel frequency. It is necessary to follow the same tuning sequence for each of the ten channel frequencies available to the receiver.

To set the receiver for the next channel frequency rotate the channel selector switch (1) to the next position by means of the flat flange on the panel connected to this switch. The two selector dials (2) will then rotate to a new position for adjustment to the second channel frequency.

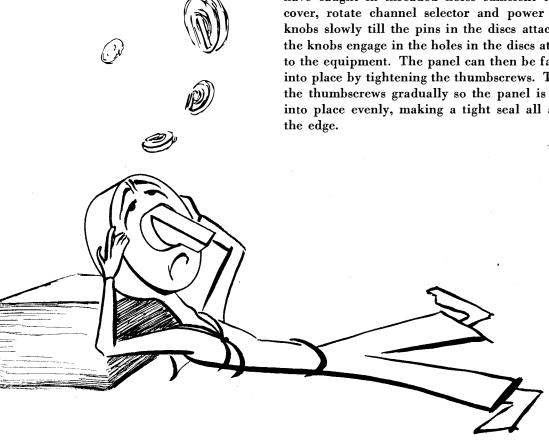

The same tuning sequence is again followed step by step in making the adjustments for this second channel frequency as given with the first channel frequency settings.

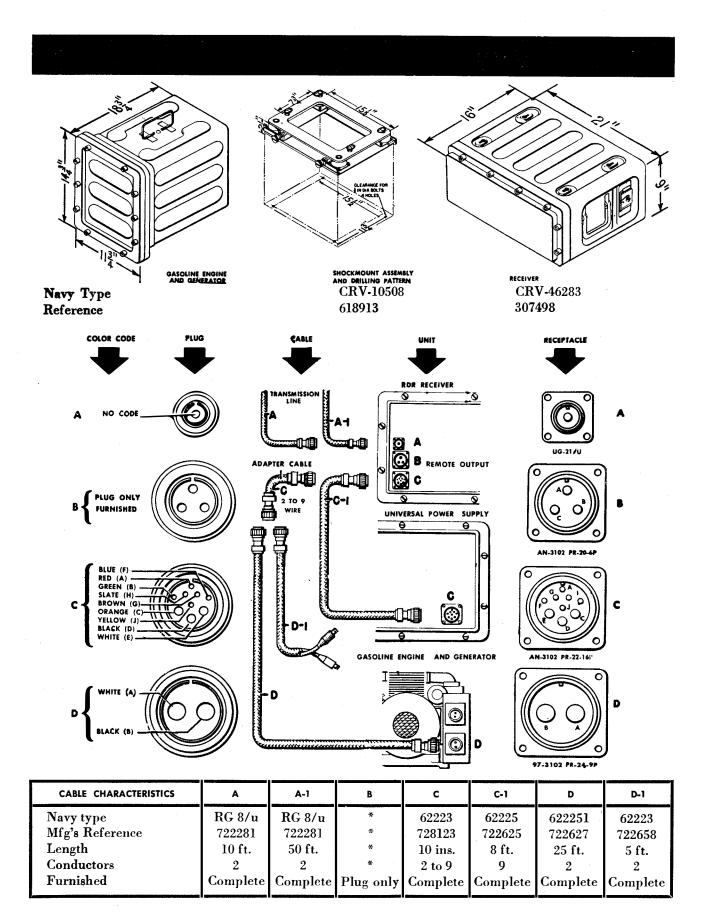

By repeating the procedure, the entire ten channels are tuned. The operation of the tuning mechanism should be checked by picking up a signal on

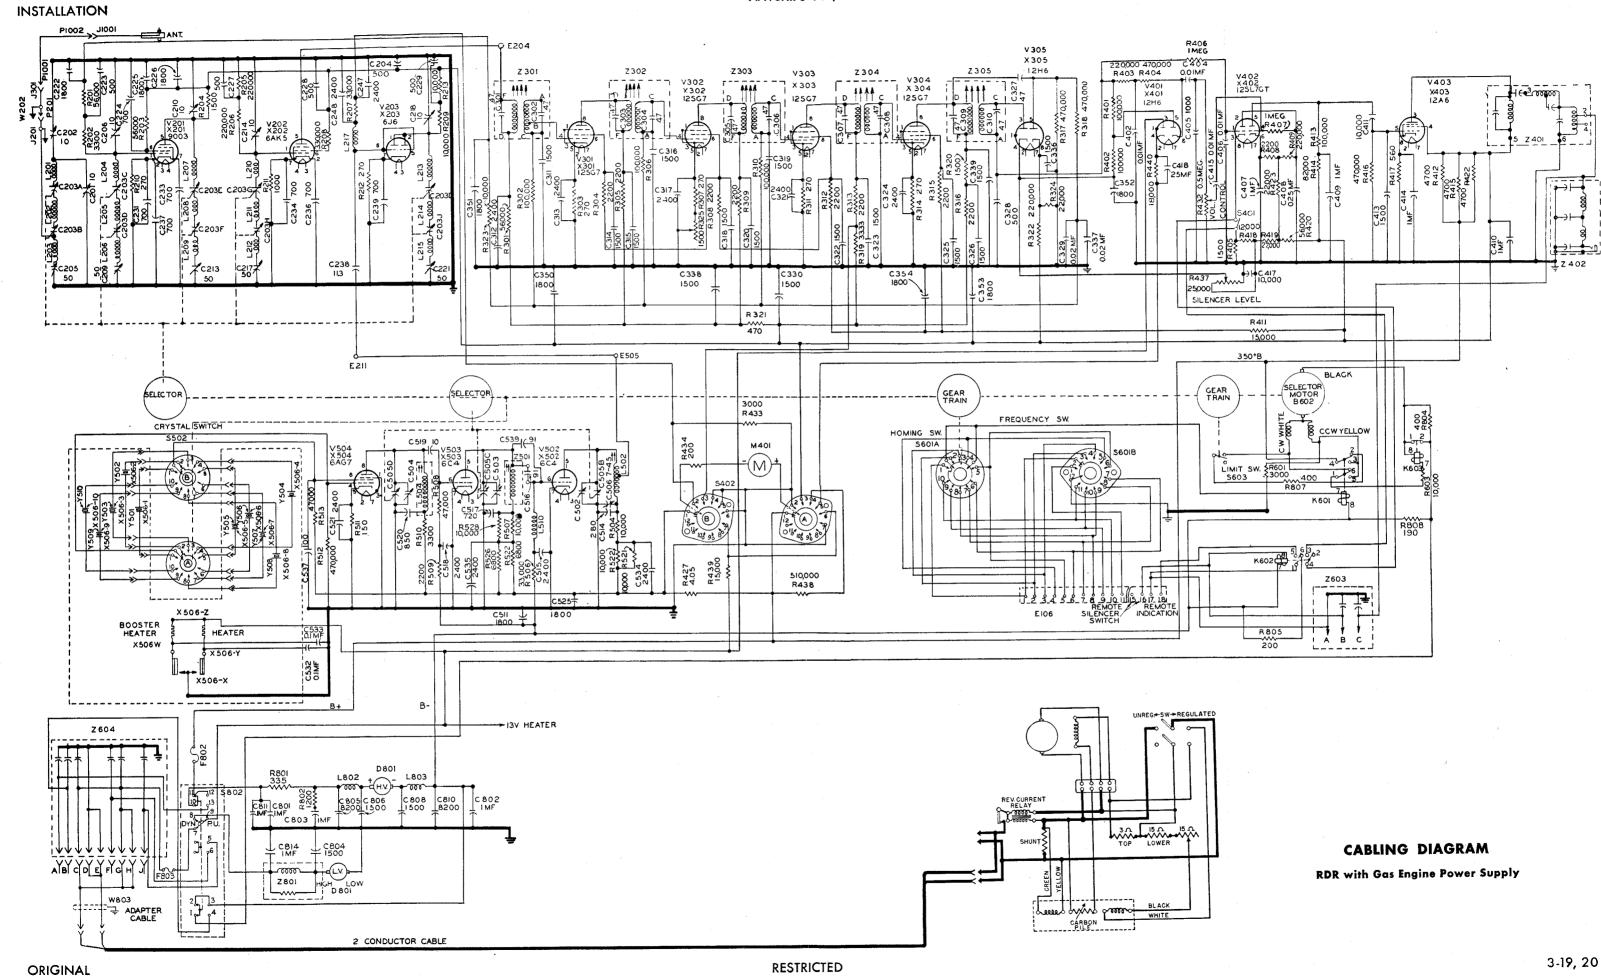

one frequency channel, switching to another frequency to cut it off and then switching back to the channel on which signal was received.

The cover, with soft rubber gasket in place, may now be replaced over the selector dials, making certain vernier knob has been returned to its clip on the panel. Hold the cover in place while starting the mounting thumbscrews and when screws have caught in threaded holes sufficient to hold cover, rotate channel selector and power switch knobs slowly till the pins in the discs attached to the knobs engage in the holes in the discs attached to the equipment. The panel can then be fastened into place by tightening the thumbscrews. Tighten the thumbscrews gradually so the panel is pulled into place evenly, making a tight seal all around the edge.

WARNING

The RDR equipment employs voltages which are dangerous to operating personnel and may cause fatalities if safety regulations are not strictly obeyed.

Don't Touch Live Circuits—Remove all source of power before changing tubes or making adjustments inside the equipment. Capacitors may retain dangerous charges after power is off, so discharge and ground circuits prior to touching them.

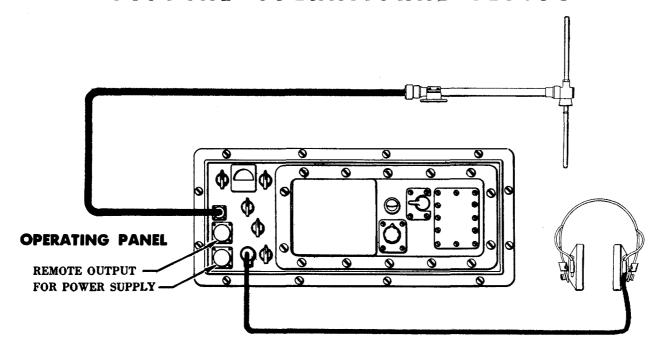

Don't Service or Adjust Alone—Check resistance and continuity rather than voltage whenever possible. The attention of officers and operating personnel is directed to Chapter 67 of Bureau of Ships Manual or superseding instructions on the subject of Radio-Safety precautions to be observed.

TYPICAL OPERATIONAL SETUPS

OPERATION OF RDR RECEIVER

The operation of the RDR receiver is similar in most respects to the procedure followed in handling the MAR equipment during reception. Lacking many of the complications presented by the involved switching system in the MAR, its operation requires a minimum of adjustments on the part of the operator.

Since the receiver is tuned by a preset selector system controlled by a rotary switch, the selection of operating frequency requires only that the switch be rotated to the desired channel position. The rest of the operating procedure is then a matter of adjusting the volume of output and degree of silencing action to suit conditions.

The method of starting the equipment will vary slightly according to the type of installation and the source of power used. Thus, in a permanent installation where the receiver is used with MAR equipment powered by a universal power unit operating from power mains, starting the equipment requires only the switching on of power to the receiver. Such an installation is shown in the illustration where the controls for the RDR are indicated in black.

With the equipment connected as shown, it is necessary to switch on the MAR before operating the RDR receiver. The control circuit that operates the input current relay of the power supply unit is connected to the receptacle into which the MAR power cable is plugged. After switching on the MAR, the power switch on the panel of the RDR can be moved to the PU position to switch on the RDR.

Should it be necessary to operate the RDR from the power supply unit without the MAR, the power supply cable to the RDR must be plugged into the receptacle on the power unit to which the MAR cable is usually connected. With this arrangement the switch on the RDR receiver will then control the power supply unit. Starting the RDR receiver when the source of power is 13V direct current from the gas engine driven generator becomes more complicated since it involves starting of the generator unit before power is available.

Before starting engine, check oil level by means of plug gauge on side of engine crankcase and add oil of proper grade (S.A.E. 20) if necessary to bring it up to the full point. Check fuel tank and fill if necessary. Make sure that fuel valve under tank is open, that switch on control box is in RADIO position. Place ignition switch, on flywheel housing, in ON position and close choke on carburetor air intake.

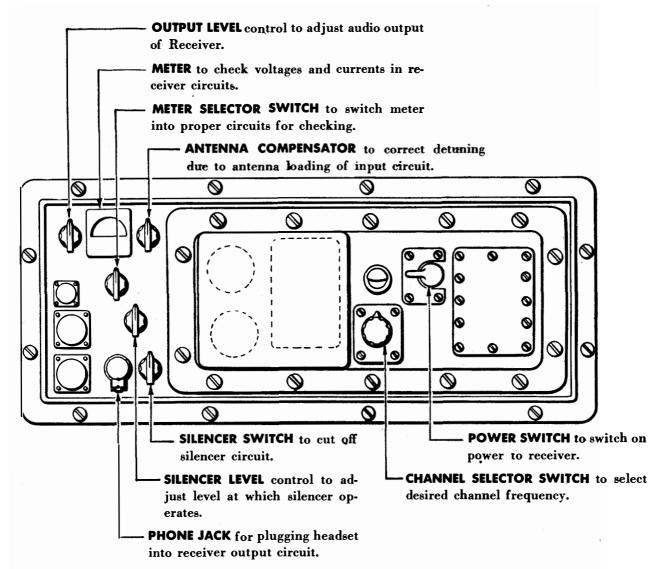

Wrap starter rope around grooved pulley on end of engine housing and while steadying engine with left hand or foot exert a quick pull on the rope. If engine starts, open choke valve.

If engine does not start, open choke valve and repeat spinning of engine with rope until it starts. Should engine fail to start after several attempts, prime it again by closing choke for one pull of the starter rope and opening it for several trials.

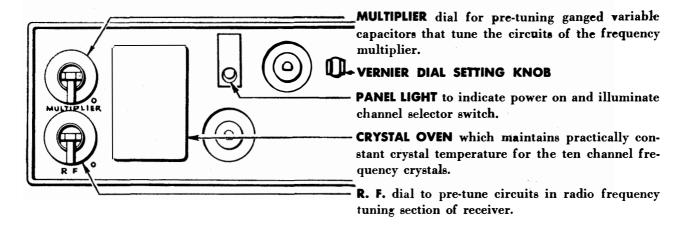

After the engine has started, allow it to warm up for several minutes until it is running smoothly.

With the gas engine unit in operation, the RDR receiver may then be switched on by moving the power switch on the panel to the DYN position.

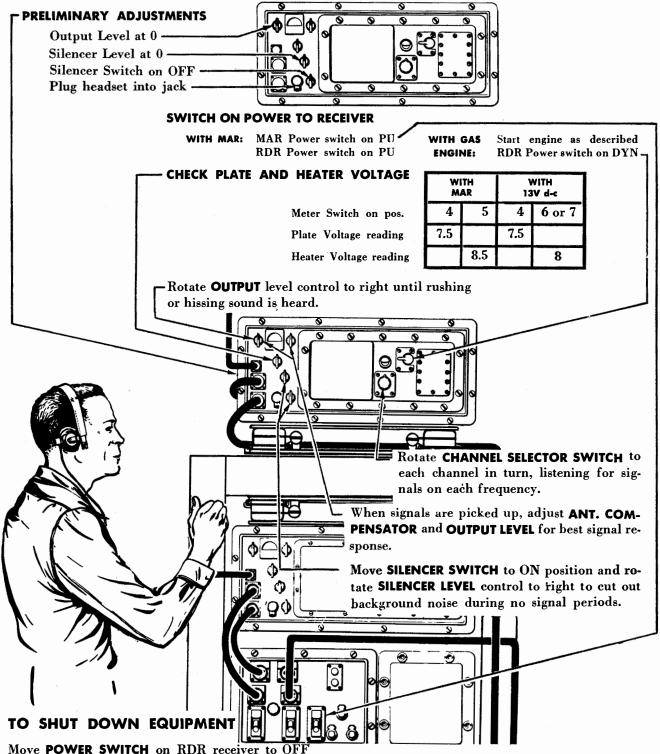

RECEIVER PANEL CONTROLS

SELECTOR PANEL FITTINGS

OPERATING PROCEDURE

Move **POWER SWITCH** on RDR receiver to OFI position.

Return SILENCER LEVEL CONTROL to 0 and SI-LENCER SWITCH to OFF position to assure reception of weak signals when operation is resumed. Shut down GAS ENGINE GENERATOR, if used, by means of switch on flywheel housing.

Move **POWER SWITCH** on MAR to OFF position unless this equipment is to continue in use.

OPERATOR'S DONT'S

leave Silencer switch at on or Silencer level at other than 0 when the receiver is switched off.

BECAUSE this may cause the loss of a weak signal when operation is resumed.

DONT operate the receiver if the panel light does not light.

BECAUSE this lamp is in a filament heater branch and will unbalance the tube voltage if burnt out.

DON'T operate the equipment with heater voltages above normal.

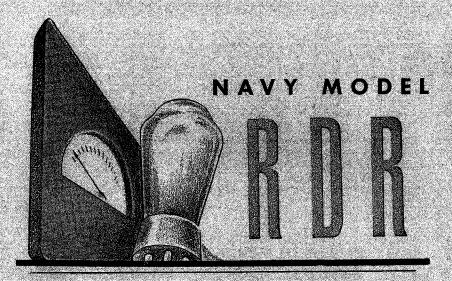

BECAUSE the overvoltage will shorten tube life. Necessary adjustment can be made at rheostat on generator control box.

DON'T neglect gas engine lubrication.

BECAUSE rapid wearing of parts and early failure of the unit is certain to result if lubricating chart in Section 5 is not followed in detail.

SAFETY NOTICE

The RDR equipment employs voltages which are dangerous to operating personnel and may cause fatalities if safety regulations are not strictly obeyed.

Don't Touch Live Circuits—Remove all source of power before disconnecting cables or making adjustments inside the equipment. Capacitors may retain dangerous charges after power is off so discharge and ground circuits prior to touching them.

Check resistance and continuity rather than voltage whenever possible.

The attention of officers and operating personnel is directed to Chapter 67 of Bureau of Ships Manual or superseding instructions on the subject of Radio-Safety precautions to be observed.

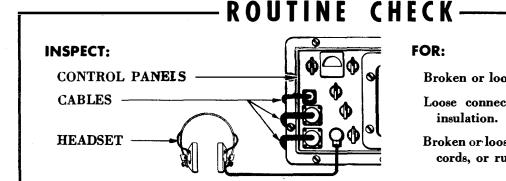

NOTICE

An approved poster illustrating the rules for resuscitation by the prone pressure method shall be prominently displayed in each Radio, Radar or Sonar Enclosure. Posters may be obtained upon request to the Bureau of Medicine and Surgery.

OPERATOR'S MAINTENANCE

In common with all electronic apparatus, the RDR radio equipment is subject to minor derangement and tube deterioration that can be located and corrected by the operator without requiring the services of a radio technician. Despite every precaution in manufacture, it is the attention and care given the equipment by the operator that determines the degree of satisfactory operation and the life of the equipment and accessories.

The operator should then be constantly alert for symptoms of minor defects that can become major difficulties if permitted to take their course. The adoption of a checking routine when taking over the equipment is recommended as the simplest and surest way of locating and correcting improper functioning to avoid equipment failures. The following routine check is recommended as a quick method of locating trouble before it becomes serious. The number in the last column of the chart indicates the page on which full details of causes and necessary corrections are given when the test indicates trouble requiring more information than given in the chart.

FOR:

Broken or loose knobs or switches.

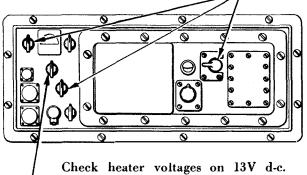

Loose connectors, kinks or worn insulation.

Broken or loose parts, broken plugs, cords, or rubber guards cracked.

RECEIVER PANEL

WHAT TO CHECK

With Silencer and Output Level at 0, switch power onto the equipment.

HOW TO CHECK

• Panel light should glow. On 13V d-c. Dynamotor can be heard operating by placing ear close to modulator-dynamotor panel.

NOTE any unusual symptoms as excessive hum or noise in the equipment.

Move meter selector switch to positions 6 or 7 depending on polarity of power supply.

On Universal power supply, position 5 is used for this check.

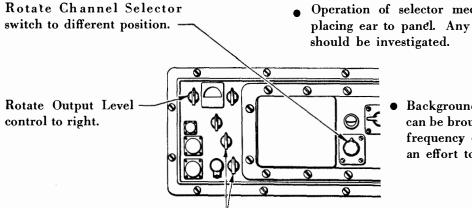

Check high voltage by placing meter switch on position 4.

5-2

- Reading of 8 should be obtained on the meter.
- Reading of 7.5 should be obtained on the meter.
- Reading of 7.5 should be obtained on the meter.

WHAT TO CHECK

HOW TO CHECK

Operation of selector mechanism can be checked by placing ear to panel. Any hesitancy or unusual sounds

> Background noise should increase and can be brought up quite loud and several frequency channels may be checked in an effort to pick up signals.

Move Silencer switch to ON and rotate Silencer control to right.

 Background noise should be eliminated with no signals. Always keep Silencer control below point where it would cut off weak signals.

GAS ENGINE GENERATOR UNIT

The gas engine unit furnished with the receiver should be checked over daily to assure it is in operating condition. The following routine is recommended to locate defects and prevent failure of the equipment.

WHAT TO CHECK	HOW TO CHECK	REFER
Check gas engine, examining carefully for loose parts or fittings. Check fuel supply and oil level in engine. Examine air filter and muffler for any obstruction.	Tighten any loose bolts. Fill fuel tank. Add oil if necessary to bring up to proper level. Excessive use of oil should be noted as it indicates leaks in the crankcase or worn piston rings.	Sec. 6
Start engine and note operation under load.	Erratic operation may be due to leaks in the intake fittings or defective spark plug. Change plug if showing signs of burning or heavy carbon deposits.	Sec. 7
Check switch on control box.	Make certain switch is on Radio position for operation of radio receiver.	Sec. 6

FUSE FAILURE

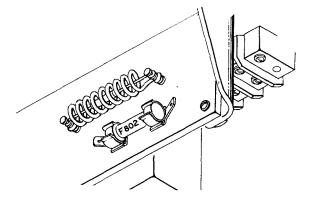

SYMPTOMS: On 13V. d-c panel light out.

Dynamotor not operating.

No meter reading on positions 5 and 6 of meter switch.

CAUSE: Low voltage fuse, F803 defective.

CORRECTION: Switch off power, loosen screws around panel of receiver and withdraw chassis, half way. Replace with 30A fuse from spares. Fuse is located in dynamotor section at left.

SYMPTOMS: Panel light on.

Dynamotor operating.

No meter reading with Meter switch on position 4.

Channel selector motor will not function.

CAUSE: High voltage fuse, F802, defective.

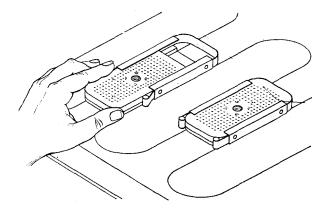

correction: Proceed as before, the fuse being located on the terminal board beneath the chassis. Replace with 1A fuse from spares. This fuse is located beneath the dynamotor section at the rear end of the left hand terminal board.

SILICA GEL DRYER UNIT

Whenever there is occasion to remove the chassis of the RDR radio equipment from the case it is advisable to check the dryer units clipped to the bottom of the cases. The case contains two units fitting into clips, and spare units in sealed packages are provided with the accessories.

Remove the dryer cartridge from the clip and inspect the small mica window on one side of the unit. The contents of the cartridge will be visible and if of a light blue or grayish color, the unit is still effective and may be placed back in service.

Should the grains show a faint pink color it indicates they are saturated with moisture and the unit should be replaced. Remove one of the spare dryer cartridges from its container by pulling loose the sealing strip around the edge of the tin box enclosing the cartridge. Insert the fresh dryer cartridge into the clip in the bottom of the equipment case. Save the used cartridge and can.

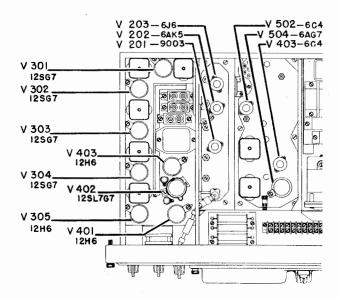

The dryer cartridge can be reclaimed by heating in an oven at a temperature of 300° F. for a period of three hours. This will drive all the moisture from the silica gel granules and the cartridge can be placed in the can and the whole sealed with the tape around the edge for future use.

TUBE FAILURE

The most common cause of tube failure is the decrease of electronic emission from the cathode with prolonged use. This is usually accompanied by a gradual reduction in signal strength. To obtain maximum tube life it is necessary to hold the heater voltages at their rated values and avoid overvoltages that shorten the life of the tubes by causing abnormal cathode emission. Maintaining proper heater circuit voltage is an important factor in the proper operation of the equipment.

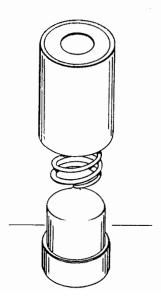

Normal loss of cathode emission is usually detected and corrected by the checking routine of preventive maintenance. Under some conditions, particularly from extreme shock, a tube may fail suddenly, either from opening of heater circuit or other mechanical disturbance of its elements. In such cases the illustration is a guide to locating the defective tube and making replacement, which may have to be done by the operator in an emergency.

The illustration above shows the location and type of all tubes used in the equipment. The spare tubes furnished with the RDR consists of one tube

of each type used and when more than one tube of a given type is suspected as the cause of trouble it will be necessary to replace them one at a time till the defective tube is located.

REPLACING TUBES

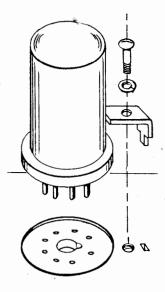

Several methods of clamping the tubes in place in their respective sockets are employed in the RDR equipment. It is important in replacing tubes to replace or tighten the clamps when tubes are replaced to prevent vibration loosening the tubes in the sockets.

The smaller tubes, particularly in the R-F and Multiplier sections, should be handled carefully to prevent damage

to the wire prongs. These tubes are held in place by springs enclosed in the tube shield. The shields are fitted with a bayonet joint and are removed by rotating the shield to the left till it can be removed from the base. After inserting the tube, the shield should always be replaced before testing the operation of the equipment.

The metal enclosed tubes are clipped into place by an L shaped clamp that is held in place by a machine screw. To release the clamp, the machine screw is loosened by a screwdriver till the clamp will raise far enough to free the lower end from the hole in the chassis and permit the clamp to be turned a quarter turn to free it

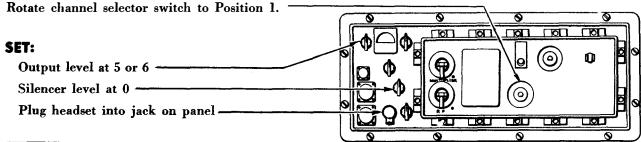

from the tube base. The tube may then be withdrawn from its socket and tested or replaced as necessary. The clamp is again swung back into position and the screw tightened to lock the tube in place.

RECEIVER TUNING CHART

PRELIMINARY ADJUSTMENTS

- Remove cover of selector panel.
- Switch on MAR equipment if Universal Power supply is used.
- Start gas engine if operating from generator.
- Switch power on to receiver and allow to heat 5 minutes.

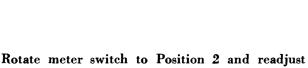

TUNING

Rotate meter switch to Position 1

Unlock Multiplier dial by raising lever straight out from dial. Insert vernier knob into hole adjacent to dial and rotate the dial slowly until a reading of 5 to 7 is obtained on the meter. Do not lock dial.

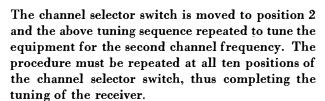

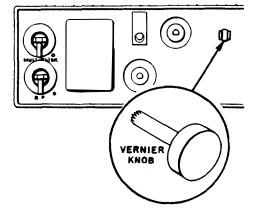

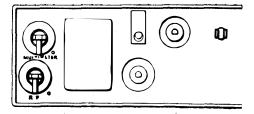

Rotate meter switch to Position 3 and unlock R. F. dial by raising lever. Insert vernier knob and rotate dial slowly and note increase in background noise in receiver. Maximum noise with a minimum meter reading of 7 indicates proper resonance. The dial is then locked. This completes tuning for the first channel frequency.

The operation of the tuning mechanism can be checked by picking up a signal on one frequency channel, switching to another frequency to cut it

off and then switching back to the channel on which the signal was received.

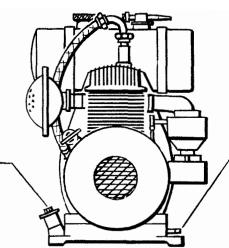

The cover is then replaced over the selector panel, making certain the vernier knob is fitted into the clip on the panel. Start thumbscrews on cover into tapped holes in panel frame to hold cover in place and rotate channel selector switch and power switch knobs till the pins and holes in the coupling disks on knobs and switches engage and then tighten cover into place with thumbscrews.

LUBRICATION CHART

GAS ENGINE GENERATOR

Keep filled to level of plug opening, use oil of proper grade as indicated in table below. Replace plug tightly and wipe off excess oil.

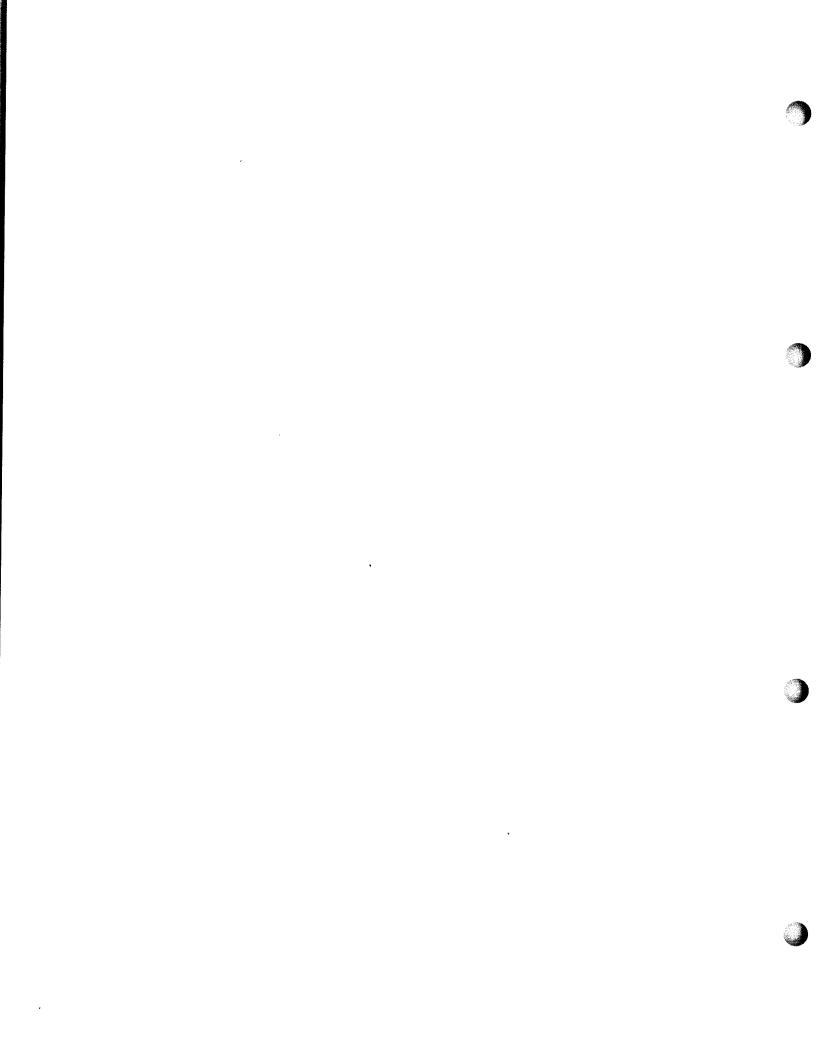

Oil governor linkage when refilling crankcase.

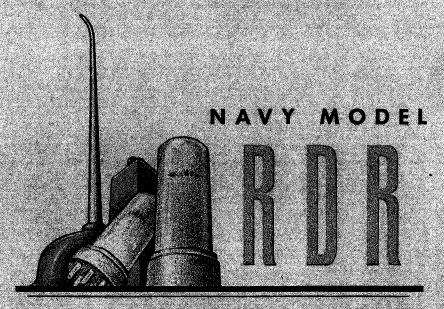

Drain crankcase and refill with fresh oil after every 25 hours of operation. Drain only when engine is warm and make certain plug is tight before refilling crankcase.

CRANKCASE LUBRICANT

NAVY SYMBOL NO. 2190 OR NO. 2135				
GRADE	TEMPERATURE			
SAE 20	Summer and winter down to—10° F.			
10 W—70% Kerosene—30%	Down to—30° F.			
10 W—60% Kerosene—40%	Down to—40° F.

SERVICING RDR EQUIPMENT

It has been found that equipment breakdown may be minimized or eliminated by periodic inspection and servicing. Slight symptoms usually give warning of operating irregularities which preventive maintenance, systematically employed, will discover and correct. Increased equipment life and greater overall efficiency will result if the preventive maintenance charts in this section are conscientiously followed.

The removal of dust and dirt from equipment is usually a "must" on very-high-frequency apparatus, but the sealed RDR case makes this chore unnecessary. Except where itemized under specific component headings, cleaning should present no problem.

The relative importance of an antenna system to the rest of the radio equipment increases considerably at the operating frequencies of the RDR receiver. Therefore, the value of the notes on antenna maintenance will readily be seen.

Preventive maintenance, as applied to tubes, involves only the periodic checking of efficiency to prevent burnouts. The gradual loss of output that precedes tube failure should be heeded and replacements made before such failure occurs.

The cabling used with the RDR, will probably receive the most abuse and, accordingly, will be subject to more breakdown possibilities. While all cables and connectors have been designed to function under severe operating conditions, the prompt remedial treatment of slight physical damage will minimize wiring failure. The maintenance steps outlined will aid in discovering and eliminating potential trouble spots.

PREVENTIVE MAINTENANCE CHART

	UNIT	PROCEDURE
WEEKLY CHECK	ANTENNA	Check all mounting bolts or clamps for rigidity. Check radiating rods for damage and tightness.
		Check coaxial connectors for tightness.
		Check coaxial cable to be sure that no part of the cable lies parallel to the radiating rods within a distance of five feet.
	GAS ENGINE GENERATOR	MAGNE10 LEAD VILV
		MUFFLER ————————————————————————————————————
		Tighten all bolts and grounding strap.
		Clean around carburetor to keep the air intake jets from becoming clogged.
		Wipe off magneto lead to spark plug.
		Keep wiring free from oil, water, or grease.
		Wipe off screen in end bell of generator to keep air passages clean.
		Inspect muffler for clogging of exhaust holes. Stoppage of these holes may cause overheating or render engine inopera- tive.
		Inspect control box switch as to proper position for type of operation desired, i.e., "Radio" or "Battery Charge."
		While charging batteries, listen for intermittent clicking of reverse current relay in control box. If relay is heard, turn rheostat at control box to produce 13.3 volts at generator terminals. Continued relay operation at adjusted higher voltage output localizes trouble in control box circuit. (Note: Clicking of relay is normal when batteries are fully-charged.)

	UNIT	PROCEDURE
25 HOUR CHECK	GAS ENGINE GENERATOR (Cont'd)	Change crankcase oil after each 25-hour operating period and refill with one pint of oil suitable for climatic conditions as indicated on lubrication chart on page 5-7. Drain oil while engine is warm since more complete drainage is obtained and accumulated sediment and foreign matter will be removed more effectively.
50 HOUR CHECK		SPARK PLUG HEAD AIR FILTER
		Remove spark plug and examine porcelain. Discard plug if porcelain is cracked and replace with new plug and gasket from spares. If plug points are fouled, clean and reset points to 0.020 inches. (Frequent fouling of points requires carburetor adjustment. See Section 7.) Remove head and clean carbon from head, cylinder, piston, and valves. The presence of heavy carbon deposits is evidenced by difficulty in starting and by pounding or knocking under load.
		Remove air cleaner filter cartridge and inspect. If dirty, replace with new cartridge from spares. Replace oftener, if required, under unusually dusty or dirty operating conditions.
75 HOUR CHECK		Adjust valve clearance and grind valves.

UNIT **PROCEDURE** MONTHLY **CHECK** RECEIVER Remove chassis from case and tighten all terminal strip mounting bolts and all connections to strips. Tighten all selector bolts and bolts holding selectors to chassis. Tighten all setscrews on gear linkage system and from gearing to part operated. Tighten bolts holding dynamotor in place. Inspect rubber mounts at same time for any appearance of cracking. Inspect rubber gaskets behind panels and under metal panel covers for breaks or excessively deep ridges. Inspect all flexible rubber sheaths around switches for cracks or breaks. Insert headset plug in jack for test of rubber seal around plug. Looseness indicates worn seal and replacement is necessary. See that hinge cover fits snugly with plug removed. Brown or charred insulation is an obvious warning and all components in the circuit should be checked for causes. Check cables at points of attachment to connectors for evidence of cracks or breakage of rubber seal that may develop into damage to cable wiring. If cracks are present, repair by replacing rubber seal. Inspect plug pins for corrosion. Clean with crocus cloth or fine sandpaper. (A rubber eraser, with a hole bored in it, twisted around a pin several times makes a good cleaner.) Use carbon tetrachloride afterward. See that fuses and clamp-type resistors are secure in clamps and that clamps are tight.

MONTHLY CHECK (Cont'd)

UNIT	PROCEDURE
RECEIVER (Cont'd)	Visually inspect all resistors and capacitors for signs of any spots, discoloration, bulging, or leakage. This indicates deterioration or a partial breakdown, and such components should be checked for deviation from their design values. Circuits involved should also be checked.
	An area of discolored or oxidized metal near a component may also indicate overheating.
	Rotate wafer switches to wipe off possible oxidation. If contacts remain discolored or oxidized, rotate switch with piece of heavy paper between contacts, cleaning afterward with carbon tetrachloride.
	Rotate Silence and Output Level knobs to insure that wiping arm is not loose and is making firm contact.
	Rotate all rheostat and potentiometer arms to wipe off possible oxidation and to make certain wiping arm is making firm contact.
	Inspect silica gel units clipped in bottom of cases and replace if drying material, viewed through mica window, shows pink color.
	Check all tubes in a transconductance type tester, if possible. Tube 9003 must be checked on this type tester but the other tubes may be checked on an emission tester, if necessary. Remove tubes one at a time when testing to be certain each tube is replaced in same socket from which removed. Interchanging of tubes with same number will probably unbalance one or more stages, requiring re-alignment. Replace any tube registering below 70% of normal in tests. If emission tester is used and a tube checks normal but will not function in set, replacement is necessary.
	Tube clamps are of several types and each should be tightened carefully. Bayonet-type tube shields should be turned clockwise to tighten. A spring in the shield holds the tube in place.
	Connect power cable temporarily. Switch on dynamotor and operate selector mechanism to locate any bearing trouble, usually indicated by grinding noises, knocking, or repeated thumps.

	UNIT	PROCEDURE
MONTHLY CHECK (Cont'd)	SHOCK- MOUNTS	Put drop of oil on each pointed pin at rear of slides and on clamping screw to insure ease of operation. Check all bolts and nuts for tightness. No movement should take place at any point of attachment of assembly to receiver case or to support when case is rocked back and forth.
	SPARES	Check number of spare parts and order all components necessary to bring list up to prescribed quantities. Test all spare tubes for quality.
	ANTENNA	Wipe off insulator at base of "live" radiating rod. Inspect plugs and receptacles for dust or dirt. Clean with air blast, carbon tetrachloride, or small brush.
	GAS ENGINE GENERATOR	Inspect for wear or possible leaks in rubber gasket on door seal of carrying case. Repair or replace, if seal is not perfect. Clean gasoline strainer by removing fuel line valve from tank and washing in clean gasoline. Use air blast if washing does not remove sediment. Clean carburetor bowl of any sediment by removing drain plug on side of bowl. Test magneto output by removing shield and cable from spark plug. Holding cable by insulation to avoid shock, turn engine over with starting rope. If end of cable is held one-eighth inch from metal body of plug, a spark should appear in the gap. No spark indicates need to check magneto output if cable is undamaged. See Section 7 for magneto servicing details.

	UNIT	PROCEDURE
MONTHLY	GAS ENGINE GENERATOR	Remove end bell housing of generator and inspect commutator while in operation under load.
(Cont'd)	(Cont'd)	Remove brushes and inspect for pitting. If pitted, replace with new brushes.
		Brushes should be at least 3/8" long to make good contact. If short, replace. When removing brushes for inspection make certain each brush is returned to same holder and is in same position as when removed.
		Inspect commutator surface. A smooth, reddish-brown appearance is normal and commutator should not be touched. If surface is blackened, sand lightly with fine sandpaper.
		A grooved or worn commutator calls for replacement of generator unit from spares, and overhaul of old unit.
		Excessive sparking at commutator or chattering of brushes will result in damage to commutator surface. Replace with new generator unit from spares and overhaul old unit.
	,	If any grease or oil is noted on comutator, this indicates bearing grease seal has broken down. Remove generator and overhaul to prevent damage to unit.
٠	,	Brush-holding springs should be firm and of a length to maintain sufficient pressure on brushes. If weak, replace.
QUARTERLY CHECK	SELECTOR MECHANISM	Test for gear backlash by turning various shafts by hand. If excessive, replace gears involved.
		Inspect gears visually for signs of wear. Replace, if wear is noticeable. Lubricate as indicated on chart on page 6-10.
	WATER SEALS	With all panel covers in place and plugs inserted, apply three pounds of air pressure to case through air valve in top of case. Case should hold this pressure for 5 minutes. If a leak is indicated, attempt to locate leak by ear. If unsuccessful, place case on back with panel up and use standard soapy water test applied to all openings. Replace gaskets or repair as necessary.

·	UNIT	PROCEDURE	SEE
QUARTERLY CHECK (Cont'd)	DYNAMOTOR	Brushes in motor units (dynamotor and tuning motor) should be removed and inspected for scoring or pitting. If pitted, excessive sparking at commutator is indicated. Replace entire unit with component from spares and repair. All brushes should be at least ¾" long to make good contact. If short, replace. When removing brushes for inspection make certain each brush is returned to its holder and is in same place as before removal. Brush holding springs should be firm and of length to maintain sufficient pressure on brushes. Replace, if weak.	Sec. 7
	GAS ENGINE GENERATOR	Check magneto point setting after approximately 200 hours of operation. Set to 0.020 inches. Place drop of oil on felt oil wick under bearing pin of magneto breaker arm. Test compression by turning engine over slowly and noting resistance of compression stroke on alternate revolutions. If resistance is not noticeable, compression is poor denoting worn rings, leaky gaskets, or defective valves. Overhaul of engine is remedy. At any event, engine should be taken down and overhauled every 300 hours of operation.	Sec. 7
SEMI ANNUAL CHECK	RECEIVER	Check sensitivity and output of receiver. Realign if output is below standard. Remove dynamotor and tuning motor for overhaul and repair. Replace with spare units.	Sec. 7
	GAS ENGINE GENERATOR	Remove generator for inspection and overhaul.	

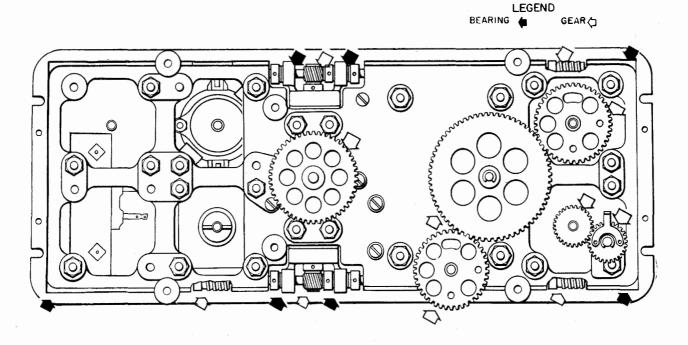

LUBRICATION CHART

SELECTOR MECHANISM

Lubricant to be used—Univis 60

Apply lubricant sparingly to teeth of gears and bearings indicated by arrows.

Carefully remove any excess and do not allow oil to drip on wiring or electrical components of the receiver circuits. All surfaces not subject to friction should be wiped free of oil with a clean cloth.

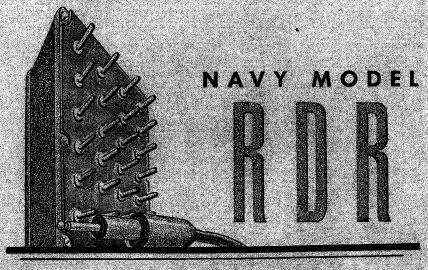

NOTE

Do not attempt to lubricate the interior mechanism of the selectors while they are in place in the chassis. Lubrication of these units is best taken care of when they are disassembled and under no conditions must oil heavier than Sperm oil be used in these units.
